## ZXLD1350

## 350mA LED driver with internal switch

## Description

The ZXLD1350 is a continuous mode inductive step-down converter, designed for driving single or multiple series connected LEDs efficiently from a voltage source higher than the LED voltage. The device operates from an input supply between 7 V and 30 V and provides an externally adjustable output current of up to 350 mA . Depending upon supply voltage and external components, this can provide up to 8 watts of output power.
The ZXLD1350 includes the output switch and a high-side output current sensing circuit, which uses an external resistor to set the nominal average output current.
Output current can be adjusted above, or below the set value, by applying an external control signal to the 'ADJ' pin.

## Features

- Simple low parts count
- Internal 30V NDMOS switch
- 350mA output current
- Single pin on/off and brightness control using DC voltage or PWM
- Internal PWM filter
- Soft-start
- High efficiency (up to $95 \%{ }^{\left({ }^{(*)}\right)}$
- Wide input voltage range: 7 V to 30 V
- 40 V transient capability
- Output shutdown
- Up to 1 MHz switching frequency
- Inherent open-circuit LED protection
- Typical 4\% output current accuracy
$\left.{ }^{*}\right)$ Using standard external components as specified under electrical characteristics. Efficiency is dependent upon the number of LEDs driven and on external component types and values.

Pin connections

The ADJ pin will accept either a DC voltage or a PWM waveform. Depending upon the control frequency, this will provide either a continuous or a gated output current. The PWM filter components are contained within the chip.
The PWM filter provides a soft-start feature by controlling the rise of input/output current. The soft-start time can be increased using an external capacitor from the ADJ pin to ground.
Applying a voltage of 0.2 V or lower to the ADJ pin turns the output off and switches the device into a low current standby state.
The device is assembled in a TSOT23-5 pin package.

## Applications

- Low voltage halogen replacement LEDs
- Automotive lighting
- Low voltage industrial lighting
- LED back-up lighting
- Illuminated signs

Typical application circuit

## ZXLD1350

## Block diagram

## ZXLD1350

## Device description

The device, in conjunction with the coil (L1) and current sense resistor ( $\mathrm{R}_{\mathrm{S}}$ ), forms a self-oscillating continuous-mode buck converter.

Device operation (Refer to block diagram and Figure 1-Operating waveforms)
Operation can be best understood by assuming that the ADJ pin of the device is unconnected and the voltage on this pin ( $\mathrm{V}_{\mathrm{ADJ}}$ ) appears directly at the (+) input of the comparator.
When input voltage $\mathrm{V}_{\mathrm{IN}}$ is first applied, the initial current in L1 and $\mathrm{R}_{\mathrm{S}}$ is zero and there is no output from the current sense circuit. Under this condition, the (-) input to the comparator is at ground and its output is high. This turns MN on and switches the LX pin low, causing current to flow from $\mathrm{V}_{\text {IN }}$ to ground, via $\mathrm{R}_{\mathrm{S}}, \mathrm{L} 1$ and the LED(s). The current rises at a rate determined by $\mathrm{V}_{I N}$ and L 1 to produce a voltage ramp ( $\mathrm{V}_{\text {SENSE }}$ ) across $\mathrm{R}_{\mathrm{S}}$. The supply referred voltage $\mathrm{V}_{\text {SENSE }}$ is forced across internal resistor R1 by the current sense circuit and produces a proportional current in internal resistors R2 and R3. This produces a ground referred rising voltage at the (-) input of the comparator. When this reaches the threshold voltage ( $\mathrm{V}_{\text {ADJ }}$ ), the comparator output switches low and MN turns off. The comparator output also drives another NMOS switch, which bypasses internal resistor R3 to provide a controlled amount of hysteresis. The hysteresis is set by R3 to be nominally $15 \%$ of $\mathrm{V}_{\text {ADJ }}$.
When MN is off, the current in L1 continues to flow via D1 and the LED(s) back to $\mathrm{V}_{\mathrm{IN}}$. The current decays at a rate determined by the LED and diode forward voltages to produce a falling voltage at the input of the comparator. When this voltage returns to $\mathrm{V}_{\text {ADJ, }}$, the comparator output switches high again. This cycle of events repeats, with the comparator input ramping between limits of $V_{\text {ADJ }} \pm 15 \%$.

## Switching thresholds

With $\mathrm{V}_{\text {ADJ }}=\mathrm{V}_{\text {REF, }}$, the ratios of $\mathrm{R} 1, \mathrm{R} 2$ and R 3 , define an average $\mathrm{V}_{\text {SENSE }}$ switching threshold of 100 mV (measured on the $I_{\text {SENSE }}$ pin with respect to $\mathrm{V}_{\text {IN }}$ ). The average output current $\mathrm{l}_{\text {OUTnom }}$ is then defined by this voltage and Rs according to:
$I_{\text {OUTnom }}=100 \mathrm{mV} / \mathrm{R}_{\mathrm{S}}$
Nominal ripple current is $\pm 15 \mathrm{mV} / \mathrm{R}_{\mathrm{S}}$

## Adjusting output current

The device contains a low pass filter between the ADJ pin and the threshold comparator and an internal current limiting resistor ( 200 k nom) between ADJ and the internal reference voltage. This allows the ADJ pin to be overdriven with either DC or pulse signals to change the $\mathrm{V}_{\text {SENSE }}$ switching threshold and adjust the output current. The filter is third order, comprising three sections, each with a cut-off frequency of nominally 4 kHz .
Details of the different modes of adjusting output current are given in the applications section.

## Output shutdown

The output of the low pass filter drives the shutdown circuit. When the input voltage to this circuit falls below the threshold ( 0.2 V nom), the internal regulator and the output switch are turned off. The voltage reference remains powered during shutdown to provide the bias current for the shutdown circuit. Quiescent supply current during shutdown is nominally $15 \mu \mathrm{~A}$ and switch leakage is below $1 \mu \mathrm{~A}$.

## Application notes

## Setting nominal average output current with external resistor $\mathbf{R}_{\mathbf{S}}$

The nominal average output current in the LED(s) is determined by the value of the external current sense resistor ( $\mathrm{R}_{\mathrm{S}}$ ) connected between $\mathrm{V}_{\mathrm{IN}}$ and $\mathrm{I}_{\text {SENSE }}$ and is given by:
$\mathrm{I}_{\text {OUTnom }}=0.1 / \mathbf{R}_{\mathbf{S}}$ [for $\mathbf{R}_{\mathbf{S}}>0.27 \Omega$ ]
The table below gives values of nominal average output current for several preferred values of current setting resistor ( $\mathrm{R}_{\mathrm{S}}$ ) in the typical application circuit shown on page 1:

| $\mathbf{R}_{\mathbf{S}}(\Omega)$ | Nominal average <br> output current (mA) |
| :---: | :---: |
| 0.27 | 370 |
| 0.3 | 333 |
| 0.33 | 300 |
| 0.39 | 256 |

The above values assume that the ADJ pin is floating and at a nominal voltage of $\mathrm{V}_{\text {REF }}(=1.25 \mathrm{~V})$. Note that $R_{S}=0.27 \Omega$ is the minimum allowed value of sense resistor under these conditions to maintain switch current below the specified maximum value.

It is possible to use different values of $R_{S}$ if the ADJ pin is driven from an external voltage. (See next section).

## Output current adjustment by external DC control voltage

The ADJ pin can be driven by an external dc voltage ( $\mathrm{V}_{\mathrm{ADJ}}$ ), as shown, to adjust the output current to a value above or below the nominal average value defined by $\mathrm{R}_{\mathrm{S}}$.

The nominal average output current in this case is given by:
$\mathrm{I}_{\text {OUTdc }}=0.08 * \mathrm{~V}_{\text {ADJ }} / \mathrm{R}_{\mathrm{S}}$ [for $0.3<\mathrm{V}_{\text {ADJ }}<2.5 \mathrm{~V}$ ]
Note that $100 \%$ brightness setting corresponds to $\mathrm{V}_{\text {ADJ }}=\mathrm{V}_{\text {REF }}$. When driving the ADJ pin above 1.25 V , $\mathrm{R}_{\mathrm{S}}$ must be increased in proportion to prevent $\mathrm{l}_{\mathrm{OUTdc}}$ exceeding 370 mA maximum.

The input impedance of the ADJ pin is $200 \mathrm{k} \Omega \pm 25 \%$.

## Output current adjustment by PWM control

## Directly driving ADJ input

A Pulse Width Modulated (PWM) signal with duty cycle DPWM can be applied to the ADJ pin, as shown below, to adjust the output current to a value above or below the nominal average value set by resistor $\mathrm{R}_{\mathrm{S}}$ :

## Driving the ADJ input via open collector transistor

The recommended method of driving the ADJ pin and controlling the amplitude of the PWM waveform is to use a small NPN switching transistor as shown below:

This scheme uses the 200k resistor between the ADJ pin and the internal voltage reference as a pull-up resistor for the external transistor.

Driving the ADJ input from a microcontroller
Another possibility is to drive the device from the open drain output of a microcontroller. The diagram below shows one method of doing this:

The diode and resistor suppress possible high amplitude negative spikes on the ADJ input resulting from the drain-source capacitance of the FET. Negative spikes at the input to the device should be avoided as they may cause errors in output current, or erratic device operation.

See the section on PWM dimming for more details of the various modes of control using high frequency and low frequency PWM signals.

## ZXLD1350

## Shutdown mode

Taking the ADJ pin to a voltage below 0.2 V for more than approximately $100 \mu \mathrm{~s}$, will turn off the output and supply current will fall to a low standby level of $15 \mu \mathrm{~A}$ nominal.
Note that the ADJ pin is not a logic input. Taking the ADJ pin to a voltage above $\mathrm{V}_{\text {REF }}$ will increase output current above the $100 \%$ nominal average value. (See graphs for details).

## Soft-start

The device has inbuilt soft-start action due to the delay through the PWM filter. An external capacitor from the ADJ pin to ground will provide additional soft-start delay, by increasing the time taken for the voltage on this pin to rise to the turn-on threshold and by slowing down the rate of rise of the control voltage at the input of the comparator. With no external capacitor, the time taken for the output to reach $90 \%$ of its final value is approximately $500 \mu \mathrm{~s}$. Adding capacitance increases this delay by approximately $0.5 \mathrm{~ms} / \mathrm{nF}$. The graph below shows the variation of soft-start time for different values of capacitor.

## Inherent open-circuit LED protection

If the connection to the LED(s) is open-circuited, the coil is isolated from the LX pin of the chip, so the device will not be damaged, unlike in many boost converters, where the back EMF may damage the internal switch by forcing the drain above its breakdown voltage.

## Capacitor selection

A low ESR capacitor should be used for input decoupling, as the ESR of this capacitor appears in series with the supply source impedance and lowers overall efficiency. This capacitor has to supply the relatively high peak current to the coil and smooth the current ripple on the input supply. A minimum value of $1 \mu \mathrm{~F}$ is acceptable if the input source is close to the device, but higher values will improve performance at lower input voltages, especially when the source impedance is high. The input capacitor should be placed as close as possible to the IC.

For maximum stability over temperature and voltage, capacitors with $\mathrm{X} 7 \mathrm{R}, \mathrm{X} 5 \mathrm{R}$, or better dielectric are recommended. Capacitors with Y5V dielectric are not suitable for decoupling in this application and should NOT be used.
A table of recommended manufacturers is provided below:

| Manufacturer | Website |
| :--- | :--- |
| Murata | www.murata.com |
| Taiyo Yuden | www.t-yuden.com |
| Kemet | www.kemet.com |
| AVX | www.avxcorp.com |

## ZXLD1350

## Inductor selection

Recommended inductor values for the ZXLD1350 are in the range $47 \mu \mathrm{H}$ to $220 \mu \mathrm{H}$.
Higher values of inductance are recommended at higher supply voltages in order to minimize errors due to switching delays, which result in increased ripple and lower efficiency. Higher values of inductance also result in a smaller change in output current over the supply voltage range. (See graphs). The inductor should be mounted as close to the device as possible with low resistance connections to the LX and $\mathrm{V}_{\text {IN }}$ pins.
The chosen coil should have a saturation current higher than the peak output current and a continuous current rating above the required mean output current.

Suitable coils for use with the ZXLD1350 are listed in the table below:

| Part No. | $\mathbf{L}$ <br> $(\mu \mathrm{H})$ | DCR <br> $(\Omega)$ | $\mathbf{I}_{\text {SAT }}$ <br> $(\mathbf{A})$ |  |
| :--- | :---: | :---: | :---: | :--- |
| MSS6132ML | 47 | 0.64 | 0.5 | CoilCraft |
|  | 47 | 0.38 | 0.56 |  |
|  | 68 | 0.58 | 0.47 |  |
|  | 100 | 0.82 | 0.39 |  |
| CD104-MC | 220 | 0.55 | 0.53 | Sumida |
| NP04SB470M | 47 | 0.27 | 0.38 | Taiyo Yuden |

The inductor value should be chosen to maintain operating duty cycle and switch 'on'/'off' times within the specified limits over the supply voltage and load current range.

The following equations can be used as a guide, with reference to Figure 1 - Operating waveforms.

## LX Switch 'On' time

$$
\mathrm{T}_{\mathrm{ON}}=\frac{\mathrm{L} \Delta \mathrm{I}}{\mathrm{~V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{LED}}-\mathrm{I}_{\mathrm{avg}}\left(\mathrm{R}_{\mathrm{S}}+\mathrm{rL}+\mathrm{R}_{\mathrm{LX}}\right)}
$$

Note: $\mathrm{T}_{\text {ONmin }}>200 \mathrm{~ns}$

## LX Switch 'Off' time

$$
\mathrm{T}_{\mathrm{OFF}}=\frac{\mathrm{L} \Delta \mathrm{I}}{\mathrm{~V}_{\mathrm{LED}}+\mathrm{VD}+\mathrm{I}_{\mathrm{avg}}\left(\mathrm{R}_{\mathrm{S}}+\mathrm{rL}\right)}
$$

Note: $T_{\text {OFFmin }}>200 n s$

## Where:

$L$ is the coil inductance (H)
$r L$ is the coil resistance $(\Omega)$
$l_{\mathrm{avg}}$ is the required LED current (A)
$\Delta I$ is the coil peak-peak ripple current (A) \{Internally set to $\left.0.3 \times \mathrm{I}_{\mathrm{avg}}\right\}$
$V_{\text {IN }}$ is the supply voltage ( V )
$\mathrm{V}_{\text {LED }}$ is the total LED forward voltage ( V )
$R_{L X}$ is the switch resistance $(\Omega)$
VD is the diode forward voltage at the required load current ( V )

## ZXLD1350

## Example:

For $\mathrm{V}_{\mathrm{IN}}=12 \mathrm{~V}, \mathrm{~L}=47 \mu \mathrm{H}, \mathrm{rL}=0.64 \Omega, \mathrm{~V}_{\mathrm{LED}}=3.4 \mathrm{~V}, \mathrm{I}_{\mathrm{avg}}=350 \mathrm{~mA}$ and $\mathrm{VD}=0.36 \mathrm{~V}$
$\mathrm{T}_{\mathrm{ON}}=(47 \mathrm{e}-6 \times 0.105) /(12-3.4-0.672)=0.622 \mu \mathrm{~s}$
$\mathrm{T}_{\text {OFF }}=(47 \mathrm{e}-6 \times 0.105) /(3.4+0.36+0.322)=1.21 \mu \mathrm{~s}$
This gives an operating frequency of 546 kHz and a duty cycle of 0.34 .
Note that in practice, the duty cycle and operating frequency will deviate from the calculated values due to dynamic switching delays, switch rise/fall times and losses in the external components.

Optimum performance will be achieved by setting the duty cycle close to 0.5 at the nominal supply voltage. This helps to equalize the undershoot and overshoot and improves temperature stability of the output current.

## Diode selection

For maximum efficiency and performance, the rectifier (D1) should be a fast low capacitance Schottky diode with low reverse leakage at the maximum operating voltage and temperature. The recommended diode for use with this part is the ZLLS1000. This has approximately ten times lower leakage than standard Schottky diodes, which are unsuitable for use above $85^{\circ} \mathrm{C}$. It also provides better efficiency than silicon diodes, due to a combination of lower forward voltage and reduced recovery time.
The table below gives the typical characteristics for the ZLLS1000:
\(\left.$$
\begin{array}{|l|l|l|l|l|l|}\hline \text { Diode } & \begin{array}{l}\text { Forward voltage } \\
\text { at 100mA } \\
(\mathbf{m V})\end{array} & \begin{array}{l}\text { Continuous } \\
\text { current } \\
(\mathrm{mA})\end{array} & \begin{array}{l}\text { Reverse Leakage } \\
\text { At 30V 85 }\end{array}
$$ <br>

(\mu \mathrm{C})\end{array}\right]\) Package | Manufacturer |
| :--- |
| ZLLS1000 |
| 310 |

If alternative diodes are used, it is important to select parts with a peak current rating above the peak coil current and a continuous current rating higher than the maximum output load current. It is very important to consider the reverse leakage of the diode when operating above $85^{\circ} \mathrm{C}$. Excess leakage will increase the power dissipation in the device.

The higher forward voltage and overshoot due to reverse recovery time in silicon diodes will increase the peak voltage on the LX output. If a silicon diode is used, care should be taken to ensure that the total voltage appearing on the LX pin including supply ripple, does not exceed the specified maximum value.

## ZXLD1350

## Reducing output ripple

Peak to peak ripple current in the LED can be reduced, if required, by shunting a capacitor $C_{\text {led }}$ across the LED(s) as shown below:

A value of $1 \mu \mathrm{~F}$ will reduce nominal ripple current by a factor three (approx.). Proportionally lower ripple can be achieved with higher capacitor values. Note that the capacitor will not affect operating frequency or efficiency, but it will increase start-up delay, by reducing the rate of rise of LED voltage.

## Operation at low supply voltage

The internal regulator disables the drive to the switch until the supply has risen above the startup threshold ( $\mathrm{V}_{\mathrm{SU}}$ ). Above this threshold, the device will start to operate. However, with the supply voltage below the specified minimum value, the switch duty cycle will be high and the device power dissipation will be at a maximum. Care should be taken to avoid operating the device under such conditions in the application, in order to minimize the risk of exceeding the maximum allowed die temperature. (See next section on thermal considerations).
Note that when driving loads of two or more LEDs, the forward drop will normally be sufficient to prevent the device from switching below approximately 6 V . This will minimize the risk of damage to the device.

## Thermal considerations

When operating the device at high ambient temperatures, or when driving maximum load current, care must be taken to avoid exceeding the package power dissipation limits. The graph below gives details for power derating. This assumes the device to be mounted on a $25 \mathrm{~mm}^{2}$ PCB with 10 copper standing in still air.

## ZXLD1350

Note that the device power dissipation will most often be a maximum at minimum supply voltage. It will also increase if the efficiency of the circuit is low. This may result from the use of unsuitable coils, or excessive parasitic output capacitance on the switch output.

## Thermal compensation of output current

High luminance LEDs often need to be supplied with a temperature compensated current in order to maintain stable and reliable operation at all drive levels. The LEDs are usually mounted remotely from the device, so for this reason, the temperature coefficients of the internal circuits for the ZXLD1350 have been optimized to minimize the change in output current when no compensation is employed. If output current compensation is required, it is possible to use an external temperature sensing network - normally using Negative Temperature Coefficient (NTC) thermistors and/or diodes, mounted very close to the LED(s). The output of the sensing network can be used to drive the ADJ pin in order to reduce output current with increasing temperature.

## Layout considerations

## LX pin

The LX pin of the device is a fast switching node, so PCB tracks should be kept as short as possible. To minimize ground 'bounce', the ground pin of the device should be soldered directly to the ground plane.

## Coil and decoupling capacitors

It is particularly important to mount the coil and the input decoupling capacitor close to the device to minimize parasitic resistance and inductance, which will degrade efficiency. It is also important to take account of any track resistance in series with current sense resistor $\mathrm{R}_{\mathrm{S}}$.

## ADJ pin

The ADJ pin is a high impedance input, so when left floating, PCB tracks to this pin should be as short as possible to reduce noise pickup. A 100 nF capacitor from the ADJ pin to ground will reduce frequency modulation of the output under these conditions. An additional series $10 \mathrm{k} \Omega$ resistor can also be used when driving the ADJ pin from an external circuit (see below). This resistor will provide filtering for low frequency noise and provide protection against high voltage transients.

## High voltage tracks

Avoid running any high voltage tracks close to the ADJ pin, to reduce the risk of leakage due to board contamination. Any such leakage may raise the ADJ pin voltage and cause excessive output current. A ground ring placed around the ADJ pin will minimize changes in output current under these conditions.

## ZXLD1350

## Evaluation PCB

The picture below shows the top copper layout of the 3 LED ZXLD1350EV2 evaluation board. This board and other evaluation boards for the ZXLD1350 are available upon request.

## ZXLD1350

## Dimming output current using PWM

## Low frequency PWM mode

When the ADJ pin is driven with a low frequency PWM signal (eg 100 Hz ), with a high level voltage $\mathrm{V}_{\text {ADJ }}$ and a low level of zero, the output of the internal low pass filter will swing between 0 V and $\mathrm{V}_{\text {ADJ }}$, causing the input to the shutdown circuit to fall below its turn-off threshold ( 200 mV nom) when the ADJ pin is low. This will cause the output current to be switched on and off at the PWM frequency, resulting in an average output current louTavg proportional to the PWM duty cycle. (See Figure 2 - Low frequency PWM operating waveforms).

Figure 2 Low frequency PWM operating waveforms
The average value of output current in this mode is given by:

## $\mathbf{l}_{\text {OUTavg }} \mathbf{0 . 1}_{\mathbf{D P W M} / \mathbf{R}_{\mathbf{S}} \text { [for } \mathrm{D}_{\text {PWM }}>001 \text { 01] }}$

This mode is preferable if optimum LED 'whiteness' is required. It will also provide the widest possible dimming range (approx. 100:1) and higher efficiency at the expense of greater output ripple.
Note that the low pass filter introduces a small error in the output duty cycle due to the difference between the start-up and shut-down times. This time difference is a result of the 200 mV shutdown threshold and the rise and fall times at the output of the filter. To minimize this error, the PWM duty cycle should be as low as possible consistent with avoiding flicker in the LED.

## ZXLD1350

## High frequency PWM mode

At PWM frequencies above 10 kHz and for duty cycles above 0.16 , the output of the internal low pass filter will contain a DC component that is always above the shutdown threshold. This will maintain continuous device operation and the nominal average output current will be proportional to the average voltage at the output of the filter, which is directly proportional to the duty cycle. (See Figure 3 - High frequency PWM operating waveforms). For best results, the PWM frequency should be maintained above the minimum specified value of 10 kHz , in order to minimize ripple at the output of the filter. The shutdown comparator has approximately 50 mV of hysteresis, to minimize erratic switching due to this ripple. An upper PWM frequency limit of approximately one tenth of the operating frequency is recommended, to avoid excessive output modulation and to avoid injecting excessive noise into the internal reference.

Figure 3 High frequency PWM operating waveforms
The nominal average value of output current in this mode is given by:

## $\mathrm{I}_{\text {OUTnom }} \approx 0.1 \mathrm{D}_{\text {PWM }} / \mathbf{R}_{\mathbf{S}}$ [for $\mathrm{D}_{\text {PWM }}>0.16$ ]

This mode will give minimum output ripple and reduced radiated emission, but with a reduced dimming range (approx.5:1). The restricted dimming range is a result of the device being turned off when the dc component on the filter output falls below 200 mV .
