## Executive Summary

This report presents a comprehensive analysis, modeling, simulation, and design optimization of the self-oscillating flyback converter, which is also known as the Ringing-Choke Converter (RCC). The self-oscillating flyback converter is a very popular topology in cost-sensitive applications such as, for example, auxiliary power supplies and mobile phone chargers due to a low component count. As a result, this circuit is designed into numerous Delta power supplies and chargers.

Although the self-oscillating flyback converter is a very simple circuit, the operation and design of the circuit is generally not well understood. The existing limited literature on this circuit only superficially addresses the operation of the circuit and its design. This lack of the full understanding of the operation and design of this popular and extensively used circuit prompted DPEL to dedicate significant resources to studying this circuit.

The major results of this study, which are included in this report, are:

- a very detailed analysis of the operation of the self-oscillating flyback converter power stage that fully explains the role of each component of the circuit, including the major parasitic components.
- The development of an accurate small-signal model of the power stage for feedback-loop design optimization.
- The development of a Saber simulation model of the circuit and its verification.
- The development of a step-by-step design procedure for the selfoscillating flyback power stage and its verification.
- The development of a detailed step-by-step feedback control procedure and its verification.

The report also presents a design example that uses the developed step-by-step design procedure. Finally, the source code of the developed Saber model and a MathCad worksheet developed to facilitate design optimization of the circuit are also included in the report.

Hopefully, the results of this study that are summarized in this report will help our engineers to come up with more cost-effective designs of the circuit by understanding its design trade-offs and by utilizing the provided design and simulation tools.

## 1. INTRODUCTION

The self-oscillating flyback converter is a very attractive circuit because of a reduced component count [1] - [2]. Generally, in a self-oscillating converter the turn-on and turn-off instants are determined solely by power stage voltage and current conditions. Therefore, the self-oscillating converter operates with a variable switching frequency. In applications which does not require a tight output regulation in a wide range of input voltage and load current, the self-oscillating flyback converter is operated in open-loop fashion. However, in applications that require a tight output regulation, a feedback control is employed. The implementation of this control is simple and cost effective since the pulse-width modulator (PWM) and switch driver are implemented discretely using a single transistor, a positive-feedback winding, and a resistor/capacitor network.

The circuit diagram of a self-oscillating flyback converter is shown in Fig. 1. The circuit in Fig. 1 has two secondary windings: output winding $\mathrm{N}_{\mathrm{S} 1}$ and feedback winding $\mathrm{N}_{\mathrm{S} 2}$. Output $\mathrm{V}_{\mathrm{O} 1}$ is tightly regulated by error amplifier $\mathrm{E} / \mathrm{A}$. The PWM modulator, which compares the error voltage $\mathrm{V}_{\mathrm{e}}$ with a voltage proportional to the switch current, is implemented discretely using a single bipolar junction transistor (BJT) and two additional resistors.

Output voltage $\mathrm{V}_{\mathrm{O} 1}$ is sensed through a resistor divider consisting of resistors $\mathrm{R}_{\mathrm{d} 1}$ and $\mathrm{R}_{\mathrm{d} 2}$, and compared at the input of a transconductance type amplifier (TL431) to a stable voltage reference located within the TL431 device. Components $\mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}$ and $\mathrm{R}_{\mathrm{EA} 1}$ are used as compensation to stabilize the voltage control loop. The difference between the sensed output voltage and voltage reference is amplified by TL431 and reflected to the primary side through optocoupler $\mathrm{IC}_{1}$ as an error current $\mathrm{i}_{\mathrm{e}}$. The error current $\mathrm{i}_{\mathrm{e}}$ is compared at the pulse width

Fig. 1 Circuit diagram of self-oscillating flyback converter.
modulator (PWM), which consists of components $\mathrm{Q}_{1}, \mathrm{R}_{\mathrm{F}}$, and $\mathrm{C}_{\mathrm{F}}$, to a voltage ramp which is proportional to switch current $\mathrm{i}_{\mathrm{S} 1}$ through resistor $\mathrm{R}_{\mathrm{S}}$.

Finally, a start-up circuit is implemented with components $\mathrm{R}_{\mathrm{ST}}, \mathrm{ZD}_{1}$ and $\mathrm{C}_{\mathrm{ZCD}}$. When the input voltage $\mathrm{V}_{\mathrm{IN}}$ is first applied, DC current is blocked by $\mathrm{C}_{\mathrm{ZCD}}$ allowing the gate of $\mathrm{S}_{1}$ to charge up to the clamp voltage set by $\mathrm{ZD}_{1}$. Once switching action begins, charge is delivered to $\mathrm{S}_{1}$ mainly by winding $\mathrm{N}_{\mathrm{S} 2}$. Therefore, it is possible to ignore the start-up resistor $\mathrm{R}_{\mathrm{ST}}$ during steady-state operation.

The self-oscillating flyback converter shown in Fig. 1 utilizes an n-channel enhancement mode metal-oxide-semiconductor field effect transistor (MOSFET) device as main switch $\mathrm{S}_{1}$ and an npn bipolar transistor (BJT) device as auxiliary switch $\mathrm{Q}_{1}$. Each transistor has different electrical characteristics and, therefore, different regions, or modes, of operation. The specific region of operation of a transistor device can be determined from it's terminal voltages and currents and an equivalent device model can be drawn for each mode of operation. The electrical characteristic curves of an n-channel MOSFET and an npn BJT, along with the equivalent device models used throughout this report, are shown in Fig. 2.

Typical output characteristics of the MOSFET device, i.e., drain current $\mathrm{I}_{\mathrm{D}}$ as a function of drain-source voltage $\mathrm{V}_{\mathrm{DS}}$ for different gate-source voltages $\mathrm{V}_{\mathrm{GS}}$, is shown in Fig. 2(a). In Fig. 2(a), three regions of operation are defined with three first-order-approximate equivalent device models for each region of operation. The first region of operation is the "off state" of the device (i.e., $\mathrm{I}_{\mathrm{D}}=0 \mathrm{~A}$ ). In this region, the three terminal device is modeled with it's input capacitance $\mathrm{C}_{\text {ISS }}$ and it's output capacitance $\mathrm{C}_{\text {oss }}$. For the ohmic region (i.e., to the left of the dotted line and $\mathrm{I}_{\mathrm{D}}>0 \mathrm{~A}$ ), the equivalent device model is the on-state resistance $\mathrm{R}_{\mathrm{DS}(\text { on })}$ of the device. Generally, this is the desired region of operation for the device in switch-mode power converter topologies. The third region of operation is the constant-current region. In this region, the current does not change as a function of $\mathrm{V}_{\mathrm{DS}}$, but rather as a function of $\mathrm{V}_{\mathrm{GS}}$. This third region of operation is modeled as a dependent current source which draws current from the drain to the source and is controlled by voltage $\mathrm{V}_{\mathrm{GS}}$.

The output characteristics of the BJT device, i.e., collector current $I_{c}$ as a function of collector to emitter voltage $V_{c e}$ for different base currents $I_{b}$, is shown in Fig. 2(a). For the selfoscillating flyback converter shown in Fig. 1, quadrants I and III of the $\mathrm{I}_{\mathrm{c}}$ vs. $\mathrm{V}_{\mathrm{ce}}$ curves are used
during a single switching period. For two-quadrant operation, five regions of operation are defined. In the first region of operation, that is for collector current $I_{c}=0 \mathrm{~A}$, a first order approximation is made that all terminals have an infinite impedance between them (since the input and output capacitances of a BJT device are small and do not play a significant role in this application). The device transitions into quadrant I or III once it's base terminal voltage exceeds it's emitter terminal or collector terminal voltage level by it's intrinsic cut-off voltage level $\mathrm{V}_{\gamma}$. Typically, voltage $\mathrm{V}_{\gamma}$ is in the 0.5 V to 0.6 V range for small-signal devices.

In quadrant I , i.e., in the region to the left of the dotted line and $\mathrm{I}_{\mathrm{c}}>0 \mathrm{~A}$, the device operates in the saturation region. In this region, $\mathrm{I}_{\mathrm{c}}$ increases linearly with $\mathrm{V}_{\mathrm{ce}}$. An equivalent device model is not shown since the circuit in Fig. 1 is generally not designed to operate in this region. The third region of operation, which lies to the right of the dotted line in quadrant I , is called the constant-current region. $\mathrm{I}_{\mathrm{c}}$ in this region does not change (ideally) as a function of $\mathrm{V}_{\mathrm{ce}}$ but only as a function of $\mathrm{I}_{\mathrm{b}}$. The equivalent device model for operation in the constant-current region of quadrant $\mathrm{I}(\mathrm{CC} 1)$ is drawn as a dependent current source that draws current from the collector to the emitter and which is controlled by base current $\mathrm{I}_{\mathrm{b}}$, and a pn diode between base and emitter. It should be noted that there exists a large current gain between $I_{b}$ and $I_{c}$ in the constant-current region of operation.

The fourth and fifth regions of operation of the device are within quadrant III. Generally, the device is said to operate in it's "inverse" mode within this quadrant. The regions of operation in quadrant III are similar to quadrant I with the exception that the collector and emitter terminals are (effectively) interchanged and that the current gain between $\mathrm{I}_{\mathrm{b}}$ and $\mathrm{I}_{\mathrm{c}}$ is much smaller.

The fourth region of operation in quadrant III is the saturation region (S3). As in quadrant $I$, $I_{c}$ changes linearly as a function of $V_{c e}$. As mentioned before, an equivalent device model is
not shown since the circuit in Fig. 1 is generally not designed to operate in this region. The fifth region of operation in quadrant III is the constant-current region (CC3). As in quadrant $\mathrm{I}, \mathrm{I}_{\mathrm{c}}$ does not change (ideally) as a function of $\mathrm{V}_{\mathrm{ce}}$ but as a function of $\mathrm{I}_{\mathrm{b}}$. The equivalent device model for operation in CC3 is drawn as a dependent current source which draws current from the emitter to the collector, and a pn diode between base and collector.

## 2. ANALYSIS OF OPERATION

In order to simplify the explanation of the converter shown in Fig. 1 during steady-state operation, several approximations have been made. The first approximation made was to neglect the leakage inductance of transformer $T_{1}$. This eliminated the need to consider the action of a voltage clamp across primary winding $N_{P}$ which is implemented to protect main switch $S_{1}$ from voltage ringings.

Fig. 3 Simplified circuit diagram of self-oscillating flyback converter.

The second approximation is to model the error current $i_{\mathrm{e}}$ as a constant-current source. This constant-current source replaces the compensated error amplifier TL431, the opto-coupler $\mathrm{IC}_{1}$, the capacitor $\mathrm{C}_{\mathrm{F}}$, and the resistors $\mathrm{R}_{\mathrm{d} 1}, \mathrm{R}_{\mathrm{d} 2}, \mathrm{R}_{\mathrm{A}}$, and $\mathrm{R}_{\mathrm{B}}$. The final approximation is to neglect the capacitance $\mathrm{C}_{\mathrm{GD}}$ between the gate and drain terminals of main switch $\mathrm{S}_{1}$. The terminal capacitances between gate and source $\mathrm{C}_{\mathrm{GS}}$ and between drain and source $\mathrm{C}_{\mathrm{DS}}$ are modeled as input capacitance $\mathrm{C}_{\text {ISS }}$ and output capacitance Coss. In addition to these approximations, it is assumed that $\mathrm{C}_{\mathrm{O} 1} \gg \mathrm{C}_{\mathrm{O} 2}, \mathrm{R}_{\mathrm{L} 1} \ll \mathrm{R}_{\mathrm{L} 2}$, The approximation $\mathrm{C}_{\mathrm{O} 1} \gg \mathrm{C}_{\mathrm{O} 2}$ implies that the ripple voltage of output $\mathrm{V}_{\mathrm{O} 2}$ is greater than the ripple voltage of main output $\mathrm{V}_{\mathrm{O} 1}$. Finally, it is assumed that rectifiers $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ are ideal (i.e., have zero forward voltage drop while conducting).

To facilitate the explanation of the converter operation, Fig. 4 shows eleven topological stages of the circuit in Fig. 1 during a switching cycle, whereas Fig. 5 shows key waveforms of the power-stage and control-stage. Note that reference directions of currents and voltages are given in Fig. 3.

Prior to $t=t_{0}$, switch $S_{1}$ is turning off because charge is drawn from the input capacitance $\mathrm{C}_{\text {ISS }}$ of main switch $\mathrm{S}_{1}$ by transistor $\mathrm{Q}_{1}$. As a result, drain-to-source voltage $\mathrm{V}_{\mathrm{DS}}$ increases towards $\mathrm{V}_{\text {IN }}+\mathrm{nV} \mathrm{V}_{\mathrm{O}}$. It is important to note that prior to $\mathrm{t}=\mathrm{t}_{0}$, voltage $\mathrm{V}_{\mathrm{CZCD}}$ of capacitor $\mathrm{C}_{\mathrm{ZCD}}$ is positive.

When, at $\mathrm{t}=\mathrm{t}_{0}, \mathrm{~V}_{\mathrm{DS}}$ reaches $\mathrm{V}_{\text {IN }}+\mathrm{nV} \mathrm{V}_{\mathrm{O}}$, rectifiers $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ start conducting. During this stage, which is shown in Fig. 4 (a), magnetizing current $i_{M}$ is instantaneously commutated from switch $S_{1}$ to output rectifiers $D_{1}$ and $D_{2}$ since it is assumed that leakage inductance $L_{l k g}$ of the

Fig. 4 Topological stages of self-oscillating flyback converter (cont'd).
transformer is zero. Due to the secondary-side parasitics such, for example, the leakage inductance and resistance of the windings (which are neglected in this analysis), the selection of the output capacitors such that $\mathrm{C}_{\mathrm{O} 1} \gg \mathrm{C}_{\mathrm{O} 2}$ causes that voltage $\mathrm{V}_{\mathrm{O} 1}$ is approximately constant while voltage $\mathrm{V}_{\mathrm{O} 2}$ increases. This increase in output voltage $\mathrm{V}_{\mathrm{O} 2}$ results in a faster decrease of current $i_{2}$ with respect to current $i_{1}$, as shown in waveforms (d) and (e) of Fig. 5. Because during this topological stage rectifier $D_{2}$ is conducting, voltage $V_{\text {RZCD }}$ across resistor $R_{Z C D}$ is equal to $\left(\mathrm{V}_{\mathrm{GS}}+\mathrm{V}_{\mathrm{S}}+\mathrm{V}_{\mathrm{CZCD}}\right) \approx-\left(\mathrm{V}_{\mathrm{GS}}+\mathrm{V}_{\mathrm{ZCD}}\right)$ since $\mathrm{V}_{\mathrm{S}} \ll \mathrm{V}_{\mathrm{GS}}+\mathrm{V}_{\mathrm{CZCD}}$. This voltage induces current $\mathrm{i}_{\mathrm{ZCD}}$ through resistor $\mathrm{R}_{\text {ZCD }}$ which discharges capacitors $\mathrm{C}_{\text {ISS }}$ and $\mathrm{C}_{\text {ZCD }}$. At the same time, transistor $\mathrm{Q}_{1}$ is off and current $i_{e}$ flows through the loop consisting of resistors $R_{F}, R_{S}$, and $R_{L 2}$. It should be

Fig. 5 Power stage and control stage key waveforms.
noted that transistor $\mathrm{Q}_{1}$ will be in the off state only if it's base-emitter voltage $\mathrm{V}_{\mathrm{Qbe}}$ is below it's cut-off voltage $V_{\gamma}$. Since from Fig. 4 (a) $V_{Q b e}=i_{e} R_{F}+i_{S 1} R_{S} \approx i_{e} R_{F}$ because $i_{S 1} R_{S} \ll i_{e} R_{F}$, transistor $\mathrm{Q}_{1}$ is off during $\mathrm{t}_{0}<\mathrm{t}<\mathrm{t}_{1}$ if $\mathrm{i}_{\mathrm{e}} \mathrm{R}_{\mathrm{F}}<\mathrm{V}_{\gamma}$. Stage in Fig. 4(a) ends at $\mathrm{t}=\mathrm{t}_{1}$ when $\mathrm{V}_{\mathrm{GS}}$ has decreased to the voltage level which is approximately one diode voltage drop ( $0.6-0.7 \mathrm{~V}$ ) below $\mathrm{V}_{\mathrm{Qbe}}$ and base-collector pn junction is forward biased.

After base-collector diode $D_{b c}$ starts conducting at $t=t_{l}$, current $i_{e}$ is divided between resistor $\mathrm{R}_{\mathrm{F}}$ and the base of $\mathrm{Q}_{1}$. Because collector-emitter voltage $\mathrm{V}_{\mathrm{Qce}}$ is negative, transistor $\mathrm{Q}_{1}$ operates in the inverse-constant-current region (CC3) and current $\mathrm{i}_{\text {Qce }}$ flows from the emitter to the collector, as shown in Fig. 4 (b). During this stage, capacitor $\mathrm{C}_{\mathrm{ZCD}}$ continues to discharge by the sum of currents $\mathrm{i}_{\mathrm{Qce}}$ and $\mathrm{i}_{\mathrm{Qbc}}$. As a result, voltage $\mathrm{V}_{\mathrm{Qbe}}$ increases exponentially as illustrated in waveform (f) of Fig. 5. At the same time, currents $i_{1}$ and $i_{2}$ continue to decrease. This stage ends at $t=t_{2}$ when rising voltage $V_{O 2}$ reaches the winding voltage $V_{2}$ and rectifier $D_{2}$ turns off.

After rectifier $D_{2}$ turns off at $t=t_{2}$, capacitor $C_{Z C D}$ continues to discharge through winding $\mathrm{N}_{\mathrm{S} 2}$, as shown in Fig. 4 (c). During this stage, current $\mathrm{i}_{1}$ continues to decrease. This stage ends at $t=t_{3}$ when current $i_{1}$ reaches zero, i.e., when magnetizing energy of the transformer is completely discharged.

Since at the beginning of the topological stage shown in Fig $4(d), t=t_{3}$, drain-to-source voltage $\mathrm{V}_{\mathrm{DS}}$ of $\mathrm{S}_{1}$ is $\mathrm{V}_{\mathrm{IN}}+\mathrm{nV}_{\mathrm{O}}$, i.e., it is higher than the input voltage $\mathrm{V}_{\mathrm{IN}}, \mathrm{C}_{\text {oss }}$ starts to resonantly discharge through magnetizing inductance $L_{M}$, as can be seen in waveform (b) of Fig. 5. As a result, primary voltage $V_{P}$ decreases causing a proportional decrease in secondary voltage $\mathrm{V}_{2}$. As the secondary voltage decreases, the voltage across $\mathrm{R}_{\mathrm{ZCD}}$ also decreases which decreases the current $\mathrm{i}_{\mathrm{ZCD}}$. This topological stage ends at $\mathrm{t}=\mathrm{t}_{4}$ when current $\mathrm{i}_{\mathrm{ZCD}}$ reaches zero.

After $t=t_{4}$, current $i_{\text {ZCD }}$ starts flowing in the opposite direction so that capacitors $\mathrm{C}_{\mathrm{ZCD}}$ and $\mathrm{C}_{\text {ISS }}$ start to charge, as shown in Fig. 4 (e). Since the increase of voltage $\mathrm{V}_{\mathrm{GS}}$ leads to the increase of collector-emitter voltage $\mathrm{V}_{\mathrm{Qce}}$, diode $\mathrm{D}_{\mathrm{bc}}$ turns off causing the turn off of transistor $\mathrm{Q}_{1}$. At the same time, capacitor Coss continues to resonantly discharge, which further decreases secondary winding voltage $V_{2}$. As a result, the voltage across resistor $R_{Z C D}$ increases which causes a further increase of current $i_{\text {ZCD }}$. This topological stage ends at $t=t_{5}$ when the voltage across the windings of the transformer become equal to zero.

After $t=t_{5}$, capacitor Coss continues to discharge and the winding voltages change polarity, as shown in Fig. 4 (f). Because in this topological stage voltage $V_{O 2}+V_{2}$, which drives current $\mathrm{i}_{\text {ZCD }}$, continues to increase, current $\mathrm{i}_{\text {ZCD }}$ also continues to increase. This increased $\mathrm{i}_{\mathrm{ZCD}}$ causes an increase of voltage $\mathrm{V}_{\mathrm{GS}}$, which in turn produces a further discharge of capacitor $\mathrm{C}_{\mathrm{OSS}}$ and consequently a further increase in the sum of voltages $\mathrm{V}_{\mathrm{O} 2}+\mathrm{V}_{2}$. This positive feedback continues until $V_{G S}$ reaches threshold voltage $V_{T H}$ at $t=t_{6}$ and switch $S_{1}$ is turned on by entering it's constant-current region.

After $t=t_{6}$, gate-source voltage $V_{G S}$ continues to increase as current $i_{\text {ZCD }}$ continues to flow through capacitor $C_{\text {ISS }}$, as shown in Fig. 4 (g). The stage in Fig. $4(\mathrm{~g})$ ends at $\mathrm{t}=\mathrm{t}_{7}$ when gate-source voltage $\mathrm{V}_{\mathrm{GS}}$ reaches the level where switch $\mathrm{S}_{1}$ begins operating in the ohmic region, i.e., when switch $S_{1}$ is fully turned on.

After switch $S_{1}$ is fully turned on at $t=t_{7}$, drain-source current $i_{S 1}$ starts increasing linearly with slope $d i_{S 1} / d t=V_{I N} / L_{M}$. As a result, voltage drop $V_{S}=i_{S_{S 1}} R_{S}$ across sensing resistor $\mathrm{R}_{\mathrm{S}}$ also increases with the same slope. This increases the potential of the source terminal of $\mathrm{S}_{1}$, which also increases the potentials of the gate terminal of $S_{1}$ and the base terminal of $Q_{1}$, as shown in waveforms (a) and (f) of Fig. 5. When at $t=t_{8}$, base-emitter voltage $V_{\text {Qbe }}$ reaches it's
cut-off voltage $\mathrm{V}_{\gamma}$, transistor $\mathrm{Q}_{1}$ starts conducting, as shown in Fig. 4 (i). It should be noted that to prevent the gate voltage of $S_{1}$ of exceeding the maximum rated voltage level, a voltage clamp (such as a zener diode) should be connected between the gate terminal of $S_{1}$ and ground. Once the gate voltage is clamped, current is diverted from input capacitance $\mathrm{C}_{\text {ISS }}$ to the voltage clamp until the gate voltage falls below the clamp voltage level.

Since after $t=t_{8}$ voltage $V_{Q b e}$ continues to increase because voltage $V_{S}=i_{S_{1}} R_{S}$ increases, base current $\mathrm{i}_{\mathrm{Qbe}}$ of $\mathrm{Q}_{1}$ increases causing the increase of current $\mathrm{i}_{\mathrm{Qce}}$. This topological stage ends at $t=t_{9}$ when current $i_{\text {Qce }}$ becomes equal to current $i_{\text {ZCD }}$ and gate-source capacitance starts discharging, as shown in Fig. 4 (j). As gate-source voltage decreases, transistor $S_{1}$ is turning off. At $t=t_{10}$, gate-source voltage $V_{G S}$ decreases to the threshold voltage $V_{T H}$ of $S_{1}$ so that $S_{1}$ is turned off.

After $S_{1}$ is turned off at $t=t_{10}$, the output capacitance $C_{\text {OSS }}$ of $S_{1}$ begins to charge so that voltage $\mathrm{V}_{\mathrm{DS}}$ begins to increase. This topological stage shown in Fig. 4 (k) ends when voltage $\mathrm{V}_{\mathrm{DS}}$ $+\mathrm{V}_{\mathrm{S}} \approx \mathrm{V}_{\mathrm{DS}}$ reaches $\mathrm{V}_{\mathrm{IN}}+\mathrm{n} \mathrm{V}_{\mathrm{O}}$. At the same time, secondary rectifier $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ start conducting and transistor $\mathrm{Q}_{1}$ turns off, which completes a switching cycle.

## 3. VERIFICATION OF ANALYSIS OF OPERATION

To verify the presented analysis of operation, Saber ${ }^{\top \mathrm{TM}}$ simulation models were developed for the self-oscillating flyback converter used as the stand-by power supply in Delta power supply DPS-250AB A. The schematic diagram of this $5 \mathrm{~V} / 2 \mathrm{~A}$ auxiliary circuit, which operates with a 310 V nominal input voltage, is included in Appendix A for reference. Note that the protection circuitry, such as over-voltage and thermal shutdown, have been excluded from these simulation models.

### 3.1. Simplified Simulation Model

The first simulation model, shown in Fig. 6, has a similar circuit schematic as the simplified circuit shown previously in Fig. 3. The differences between them are the inclusion of the start-up resistor $\mathrm{R}_{\mathrm{ST}}$, and the zener diode $\mathrm{ZD}_{1}$, which clamps the gate voltage to 18 V . For simplicity, the input voltage source is modeled with a constant DC source, rather than the bulk capacitor and rectifier front end used in the Delta circuit. It should be noted that the value of error current source $i_{e}$ was experimentally determined to maintain the appropriate output voltage.

### 3.1.1. Full Load Operation

Simulation waveforms generated using the simulation model shown in Fig. 6 at the full load condition are shown in Fig. 7. These waveforms, which are drawn using the chart function of Lotus Freelance Graphics ${ }^{\top M}$ software (to obtain a better picture quality than the quality offered by Saber Scope ${ }^{\text {TM }}$ ), show that at the full load condition, the gate-source voltage

Fig. 6 Simplified simulation model of auxiliary circuit used in Delta power supply DPS 250AB A.
$\mathrm{V}_{\mathrm{GS}}$ is clamped by the zener diode $\mathrm{ZD}_{1}$ for the majority of the on time. This is an indication that the device operates mainly within it's ohmic region, and, therefore, a higher energy conversion efficiency is achieved. The main switch $S_{1}$ is shown to turn on very near the moment that drainsource voltage $\mathrm{V}_{\mathrm{DS}}$ reaches it's resonant valley which is an indication that the power stage operates very near it's CCM/DCM boundary (i.e., the dead time $t_{D}$ is very small compared with
the switching period). This boundary operation is also evident from switch current $i_{\text {S1 }}$ and secondary current $i_{1}$ waveforms. In addition, secondary current $i_{2}$ reaches a near zero level and rectifier $\mathrm{D}_{2}$ turns off long before secondary current $\mathrm{i}_{1}$ reaches zero, as expected because $\mathrm{C}_{\mathrm{O1}} \gg$ $\mathrm{C}_{\mathrm{O} 2}$. In the control waveforms, the intersection of the base voltage $\mathrm{V}_{\mathrm{Qbe}}$ with its intrinsic cut-off voltage level $\mathrm{V}_{\gamma}$ initiates turn-on of transistor $\mathrm{Q}_{1}$, which draws current away from input capacitance $C_{\text {ISS }}$ and leads to the turn off of main switch $S_{1}$. Finally, it is shown that current $i_{\text {RF }}$, which flows through resistor $R_{F}$, is equal to the error current $i_{e}$ while switch $S_{1}$ is on, and is below current $\mathrm{i}_{\mathrm{e}}$ during the off time, since transistor $\mathrm{Q}_{1}$ operates in its inverse constant-current region as it discharges capacitor $\mathrm{C}_{\mathrm{ZCD}}$. Voltage $\mathrm{V}_{\mathrm{CZCD}}$ decreases during this time, and increase during the on time as charge is delivered through it to the main switch $\mathrm{S}_{1}$.

It should be noted that the effect of the gate-drain capacitance $\mathrm{C}_{\mathrm{GD}}$, which was not neglected in the simplified simulation model, is to introduce additional current resonances in the control circuit currents. These resonances are most apparent in waveform (g) of Fig. 7, especially at the moments of turn-off of main switch $S_{1}$, and are shown to have no effect on the fundamental operation of the circuit.

(e)

Fig. 7 Simplified simulation waveforms of the auxiliary circuit within Delta power supply DPS 250AB A operating at full load.

Fig. 7 Simplified simulation waveforms of the auxiliary circuit within Delta power supply DPS250 AB A operating at full load (cont'd).

### 3.1.2. Light Load Operation

Simulation waveforms at a light load condition (i.e., $25 \%$ full load) are shown in Fig. 8. Since the same time base was used for both Figs. 7 and 8, it can be seen that as the load decreases, the switching frequency of the converter increases, and the length of time that main switch $S_{1}$ operates in the ohmic region decreases. Because the time spent by switch $S_{1}$ in the constant-current region is nearly constant when the ripple voltage across capacitor $\mathrm{C}_{\mathrm{ZCD}}$ is small, the gate-source voltage $\mathrm{V}_{\mathrm{GS}}$ can drop below the clamp voltage level as shown in waveform (a) of Fig. 8. Switch $\mathrm{S}_{1}$ is shown to turn on after the drain-source voltage reaches its resonant valley, and dead time $t_{D}$ is slightly greater compared to full load operation.

Because at light load the current demand is decreased, the switch current $\mathrm{i}_{\mathrm{S} 1}$ and secondary winding current $i_{1}$ are decreased, whereas secondary current $i_{2}$ remains the same (since its load resistance remained unchanged). It should be noted from waveforms (d) and (e) in Fig. 5 that at light load, output rectifiers $D_{1}$ and $D_{2}$ turn off at approximately the same time. This happens because at light load the current demand on the output is decreased, while the current demand at the feedback winding stays the same.

Fig. 8 Simplified simulation waveforms of the auxiliary circuit used in Delta power supply DPS 250 AB A operating at $25 \%$ full load.

Fig. 8 Simplified simulation waveforms of the auxiliary circuit used in Delta power supply DPS 250AB A operating at $25 \%$ full load (cont'd).

As the load current decreases, error current $i_{e}$ increases, as shown in waveform (g) of Figs. 7 and 8, which results in an increase in the dc value of base-emitter voltage $\mathrm{V}_{\mathrm{Qbe}}$. As in the full load case, the turn off of switch $\mathrm{S}_{1}$ begins once voltage $\mathrm{V}_{\mathrm{Qbe}}$ reaches voltage level $\mathrm{V}_{\gamma}$, and voltage $\mathrm{V}_{\mathrm{CZCD}}$ across capacitor $\mathrm{C}_{\mathrm{ZCD}}$ charges during the on time and discharges during the off time of switch $\mathrm{S}_{1}$. However, the ripple voltage of voltage $\mathrm{V}_{\mathrm{CZCD}}$ decreases since both the on time and off time of switch $S_{1}$ are shorter.

### 3.2. Complete Circuit Model

Previously, approximations were made to simplify the circuit schematic to its fundamental components for the purpose of analysis. The simplified circuit was divided into 11 topological stages, and through the analysis of each stage, an understanding of the circuit operation as a whole was obtained. Once an understanding of the simplified circuit is obtained, the simulation waveforms of the complete circuit can be understood.

To examine the effect of the neglected components, a complete simulation model, shown in Fig. 9, was developed. The model differs from the previous simplified simulation model in that it includes the leakage inductance of the transformer $\mathrm{L}_{\mathrm{lkg}}$, the clamp circuit across winding $N_{P}$, the error amplifier TL431, the optocoupler $\mathrm{IC}_{1}$ and components $\mathrm{R}_{\mathrm{d} 1}, \mathrm{R}_{\mathrm{d} 2}, \mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}, \mathrm{R}_{\mathrm{EA} 1}$, $\mathrm{R}_{\mathrm{B}}, \mathrm{R}_{\mathrm{A}}$, and $\mathrm{C}_{\mathrm{F}}$.

### 3.2.1. Full Load Operation

With the circuit fully loaded, a time-domain transient analysis was performed and steadystate simulation waveforms were obtained. These simulation waveforms, shown in Fig. 10, are very similar to those obtained with the simplified model previously shown in Fig. 7. The

Fig. 9 Simulation model of auxiliary circuit within Delta power supply DPS-250AB A.
differences include the presence of voltage ringings in nearly every waveform, which is related to the addition of the leakage inductance of transformer $\mathrm{T}_{1}$, and a slightly decreased switching frequency, which is due in part to the loss of the RCD clamp across winding $\mathrm{N}_{\mathrm{S} 1}$. It should be noted that the leakage inductance not only resonates with circuit parasitic capacitances, but also prevents the current from commutating instantaneously from switch $S_{1}$ to rectifiers $D_{1}$ and $D_{2}$ as shown in waveforms (c), (d), and (e) of Fig. 10. It should also be noted that error current $i_{e}$ is not constant (i.e., there is a small ripple current superimposed on the dc current). This small ac current is a result of a high output voltage ripple present at $\mathrm{V}_{\mathrm{O} 2}$ which is the output that the error current is derived from.

Fig. 10 Simulation waveforms of the auxiliary circuit used in Delta power supply DPS 250AB A operating at full load.

Fig. 10 Simulation waveforms of the auxiliary circuit within Delta power supply DPS 250AB A operating at full load (cont'd).

### 3.3. Experimental Verification

Oscillograms of key power stage and control stage waveforms were obtained from Delta power supply DPS-250 AB A and compared with Saber simulation waveforms generated with the complete simulation model at full load and light load condition, as shown in Figs. 11 and 12, respectively. At both the full load and light load (i.e., $25 \%$ full load) condition, the shape and level of the simulation waveforms is very similar to the measured waveforms. At the full load condition, the switching frequency is nearly matched with a percent deviation of $9 \%$, whereas at the light load condition, the measured switching frequency is significantly lower than the simulation waveforms, with a percent deviation of $34 \%$. Generally, this deviation in switching frequency is due to additional losses within the transformer which are not modeled in the simulation, especially the losses associated with the leakage inductance of the transformer. The difference between the modeled leakage inductance and the actual leakage inductance can be seen from the slope of current $i_{1}$ in Figs. 11 and 12 as the current commutates from main switch $S_{1}$ to rectifier $D_{1}$, where a larger current slope implies a smaller leakage inductance. This deviation between simulated and measured frequency can be decreased with a more precise transformer model. However, the behavior of the circuit at light load is generally of little interest to the designer since the transformer is designed based on the full load condition and, therefore, a more advanced model is generally not needed.

Fig. 12 Measurements of key waveforms vs. Saber simulation waveforms for DPS-250 AB A operating at $25 \%$ load: (a) power stage waveforms; (b) control stage waveforms.

## 4. SMALL-SIGNAL MODEL

To achieve tight output voltage regulation and good dynamic performance in response to a system disturbance while ensuring system stability, compensation components $\mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}$, and $\mathrm{R}_{\mathrm{EA1}}$ of error amplifier TL431 shown in Fig. 1, needs to be determined. Generally, the compensation of the error amplifier is determined so that the closed-loop gain of the system has a high dc gain and an acceptable bandwidth and phase margin. However, the design optimization of the error amplifier compensation requires the knowledge of the small-signal transfer functions in the control loop.

To facilitate the design optimization of control loop, the self-oscillating flyback circuit in Fig. 1 has been simplified, as shown in Fig. 13. Based on this equivalent circuit, a small signal block diagram of the self-oscillating flyback converter shown in Fig. 14 is derived.

The block diagram shown in Fig. 14 consists of:

- Control-to-output voltage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})=\hat{\mathrm{V}}_{\mathrm{O}} / \hat{\mathrm{V}}_{\mathrm{e}}$
- Output voltage sensing gain $\mathrm{K}_{\mathrm{d}}=\hat{\mathrm{V}}_{\mathrm{l}} / \hat{\mathrm{V}}_{\mathrm{O}}$
- Error amplifier transfer function $G_{E A}(s)=\hat{V}_{E A} / \hat{V}_{1}$
- Transconductance gain $\mathrm{G}_{1}=\hat{\mathrm{i}}_{\mathrm{EA}} / \hat{\mathrm{V}}_{\mathrm{B}}$
- Opto-coupler gain $\mathrm{G}_{2}=\hat{\mathrm{i}}_{\mathrm{e}} / \hat{\mathrm{i}}_{\mathrm{EA}}$
- Transresistance gain $G_{3}=\hat{\mathrm{V}}_{\mathrm{e}} / \hat{\mathrm{i}}_{\mathrm{e}}$

The block diagram consists of inner loop $\mathrm{T}_{\text {INNER }}=\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s}) \mathrm{G}_{1} \mathrm{G}_{2} \mathrm{G}_{3}$ and outer voltage loop $T_{V}=G_{V e V o}(s) K_{d} G_{E A}(s) G_{1} G_{2} G_{3}$. Inner loop $T_{\text {INNER }}$ is formed as a result of connecting
one terminal of resistor $R_{B}$ to output voltage $\hat{V}_{O}$ and the other terminal of resistor $R_{B}$ to error amplifier voltage $\hat{\mathrm{V}}_{\mathrm{EA}}$.

The expression for power stage gain $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$, which is derived in Appendix C , is

$$
\begin{equation*}
\mathrm{G}_{\mathrm{VeVo}}(\mathrm{~s})=\mathrm{M}_{\mathrm{dc}} \cdot \frac{\left(\mathrm{~s} / \mathrm{s}_{\mathrm{z} 1}+1\right)\left(\mathrm{s} / \mathrm{s}_{\mathrm{z} 2}+1\right)}{\left(\mathrm{s} / \mathrm{s}_{\mathrm{p} 1}+1\right)\left(\mathrm{s}^{2} / \omega_{\mathrm{o}}^{2}+\mathrm{s} /\left(\mathrm{Q} \omega_{\mathrm{o}}\right)+1\right)} \tag{4.1}
\end{equation*}
$$

where:

$$
\begin{align*}
& \mathrm{M}_{\mathrm{dc}}=-\frac{\mathrm{V}_{\mathrm{IN}}}{2 \mathrm{R}_{\mathrm{S}} \mathrm{I}_{\mathrm{o}}},  \tag{4.2}\\
& \mathrm{~s}_{\mathrm{z1}}=\frac{1}{\mathrm{C}_{\mathrm{O} 1} \mathrm{R}_{\mathrm{CO} 1}},  \tag{4.3}\\
& \mathrm{~S}_{\mathrm{z1}}=\frac{1}{\mathrm{C}_{\mathrm{F}} \mathrm{R}_{\mathrm{CF}}},  \tag{4.4}\\
& \mathrm{~s}_{\mathrm{pl}}=-\frac{\mathrm{K}_{\mathrm{r}}}{\mathrm{C}_{\mathrm{O} 1}+\mathrm{C}_{\mathrm{F}}},  \tag{4.5}\\
& \omega_{\mathrm{O}}=\frac{1}{\sqrt{\frac{\mathrm{~L}_{\mathrm{F}}}{\frac{1}{\mathrm{C}_{\mathrm{O} 1}}+\frac{1}{\mathrm{C}_{\mathrm{F}}}}}},  \tag{4.6}\\
& \left.\mathrm{Q}=\sqrt{\mathrm{L}_{\mathrm{F}} \frac{\mathrm{C}_{\mathrm{F}}+\mathrm{C}_{\mathrm{O} 1}}{\mathrm{C}_{\mathrm{F}} \mathrm{C}_{\mathrm{O} 1}}} \cdot\left(\frac{1}{\mathrm{R}_{\mathrm{CO1}}+\mathrm{R}_{\mathrm{CF}}+\mathrm{R}_{\mathrm{lf}}+\mathrm{K}_{\mathrm{r}}\left(\mathrm{R}_{\mathrm{CO1}} \mathrm{R}_{\mathrm{CF}}-\frac{\mathrm{L}_{\mathrm{F}}}{\mathrm{C}_{\mathrm{O} 1}+\mathrm{C}_{\mathrm{F}}}\right.}\right)\right),  \tag{4.7}\\
& \mathrm{K}_{\mathrm{r}}=-\frac{\mathrm{I}_{\mathrm{O}} \mathrm{~N}}{\mathrm{~V}_{\mathrm{IN}}\left(1+\mathrm{N} \frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)} . \tag{4.8}
\end{align*}
$$

Fig. 13 Simplified self-oscillating flyback circuit for small-signal modeling and analysis.

Fig. 14 Small-signal block diagram of self-oscillating flyback converter.

Sensing gain $K_{d}$ is

$$
\begin{equation*}
\mathrm{K}_{\mathrm{d}}=\frac{\hat{\mathrm{V}}_{1}}{\hat{\mathrm{~V}}_{\mathrm{O}}}=\frac{\mathrm{R}_{\mathrm{d} 2}}{\mathrm{R}_{\mathrm{d} 1}+\mathrm{R}_{\mathrm{d} 2}} . \tag{4.9}
\end{equation*}
$$

As can be seen from Fig.13, transfer function $G_{1}$, which is defined as

$$
\begin{equation*}
\mathrm{G}_{1}=\frac{\hat{\mathrm{i}}_{\mathrm{EA}}}{\hat{\mathrm{~V}}_{\mathrm{B}}}=\frac{\hat{\mathrm{i}}_{\mathrm{EA}}}{\hat{\mathrm{~V}}_{\mathrm{O}}-\hat{\mathrm{V}}_{\mathrm{EA}}} \tag{4.10}
\end{equation*}
$$

can be calculated as

$$
\begin{equation*}
\mathrm{G}_{1}=\frac{\hat{\mathrm{i}}_{\mathrm{EA}}}{\hat{\mathrm{~V}}_{\mathrm{B}}}=\frac{\hat{\mathrm{i}}_{\mathrm{EA}}}{\hat{\mathrm{~V}}_{\mathrm{O}}-\hat{\mathrm{V}}_{\mathrm{EA}}}=\frac{1}{\mathrm{R}_{\mathrm{B}}} \tag{4.11}
\end{equation*}
$$

Error current $\hat{\mathrm{i}}_{\mathrm{e}}$ is related to current $\hat{\mathrm{i}}_{\mathrm{EA}}$ through transfer function $\mathrm{G}_{2}$, which is the dc current transfer ratio of the optocoupler,

$$
\begin{equation*}
\mathrm{G}_{2}=\frac{\hat{\mathrm{i}}_{\mathrm{e}}}{\hat{\mathrm{i}}_{\mathrm{EA}}}=\beta \tag{4.12}
\end{equation*}
$$

Finally, from Fig. 13, transfer function $G_{3}$, which relates error voltage $\hat{V}_{e}$ and error current $\hat{\mathrm{i}}_{\mathrm{e}}$ is

$$
\begin{equation*}
\mathrm{G}_{3}=\frac{\hat{\mathrm{V}}_{\mathrm{e}}}{\hat{\mathrm{i}}_{\mathrm{EA}}}=\mathrm{R}_{\mathrm{F}}+\mathrm{R}_{\mathrm{S}} \tag{4.13}
\end{equation*}
$$

The two loop system shown in Fig. 14 can be reduced to a single loop system, as shown in Fig. 15, by combining transfer functions $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s}), \mathrm{G}_{1}, \mathrm{G}_{2}$, and $\mathrm{G}_{3}$ into a single transfer function $G_{V_{E A V O}}(s)$,

$$
\begin{gather*}
\mathrm{G}_{\mathrm{VEAVo}}(\mathrm{~s})=\frac{\hat{\mathrm{V}}_{\mathrm{O}}}{\hat{\mathrm{~V}}_{\mathrm{EA}}}=\frac{K \mathrm{G}_{\mathrm{VeVo}}(\mathrm{~s})}{1+K \mathrm{G}_{\mathrm{VeVo}}(\mathrm{~s})}=\frac{K \mathrm{G}_{\mathrm{VeVo}}(\mathrm{~s})}{1+\mathrm{T}_{\mathrm{INNER}}},  \tag{4.14}\\
\mathrm{~K}=\mathrm{G}_{1} \mathrm{G}_{2} \mathrm{G}_{3},  \tag{4.15}\\
\mathrm{~T}_{\mathrm{INNER}}=\mathrm{KG}_{\mathrm{VeVo}}(\mathrm{~s}) . \tag{4.16}
\end{gather*}
$$

 which is less than 1. Also, because of inner loop $T_{\text {INNER, }}$ poles of $G_{V_{E A V O}}(s)$ are shifted to higher frequencies, as illustrated in Fig. 16. Figure 16 shows gain plots of transfer function $\mathrm{KG}_{\mathrm{VeVo}}(\mathrm{s})$, $1+\mathrm{T}_{\text {INNER }}$, and transfer function $\mathrm{G}_{\mathrm{VEAVo}(\mathrm{s}) \text {. As can be seen from Fig. 16, transfer function }}$ $G_{\text {VEAVO }}(s)$ has pole $f_{p 1}^{*}$ which is located at the cross-over frequency $f_{\text {INNER }}$ of loop $T_{\text {INNER. }}$. It can be shown that the frequency of this pole is related to the frequency of pole $f_{p 1}$ of power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$ as

$$
\begin{equation*}
\mathrm{s}_{\mathrm{p} 1}^{*}=\left(1+\mathrm{KM}_{\mathrm{dc}}\right) \mathrm{s}_{\mathrm{p} 1} \approx \mathrm{KM}_{\mathrm{dc}} \mathrm{~s}_{\mathrm{p} 1} \tag{4.17}
\end{equation*}
$$

It should also be noted that inner loop $\mathrm{T}_{\text {INNER }}$ shifts only poles of power stage transfer function $G_{\mathrm{VeVO}_{0}}(\mathbf{s})$ which are within the bandwidth $f_{\text {INNER }}$ of $\operatorname{loop} \mathbf{T}_{\text {INNER. }}$. In addition, it can be shown in Appendix C that locations of zeroes of power stage transfer function $\mathbf{G}_{\mathrm{VeVo}_{\mathbf{0}}}(\mathbf{s})$ are not affected by the existence of the inner loop.

(a)

(b)

Fig. 15 Small-signal block diagram of self-oscillating flyback converter: (a) complete block diagram; (b) simplified block diagram.

Fig. 16 Gain plots of power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s}), 1+\mathrm{T}_{\text {INNER }}$, and transfer function $G_{V_{E A} V_{o}}(s)$.

As a result, the zeroes of transfer function $G_{V_{E A V O}}(s)$ coincide with the zeroes of power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$.

Assuming that only pole $f_{p 1}$ of power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$ is within the bandwidth $f_{\text {INNER }}$ of loop gain $T_{\text {INNER }}$, as shown in Fig. 16, transfer function $G_{V_{E A V O}}(s)$ can be expressed as

$$
\begin{equation*}
\mathrm{G}_{\mathrm{V}_{\mathrm{EA} V \mathrm{Vo}}(\mathrm{~s})}=\frac{\mathrm{KM}_{\mathrm{dc}}}{1+\mathrm{KM}_{\mathrm{dc}}} \cdot \frac{\left(\mathrm{~s} / \mathrm{s}_{\mathrm{z} 1}+1\right)\left(\mathrm{s} / \mathrm{s}_{\mathrm{z} 2}+1\right)}{\left(\mathrm{s} / \mathrm{s}_{\mathrm{p} 1}^{*}+1\right)\left(\mathrm{s}^{2} / \omega_{\mathrm{o}}^{2}+\mathrm{s} /\left(\mathrm{Q} \omega_{\mathrm{o}}\right)+1\right)} \tag{4.18}
\end{equation*}
$$

By defining transfer function $\mathrm{G}_{\mathrm{V}_{\mathrm{EAVO}}}(\mathrm{s})$, the system is reduced to a single loop system with loop gain

$$
\begin{equation*}
\mathrm{T}_{1}=\mathrm{K}_{\mathrm{d}} \mathrm{G}_{\mathrm{EA}}(\mathrm{~s}) \mathrm{G}_{\mathrm{VEAVO}}(\mathrm{~s}) . \tag{4.19}
\end{equation*}
$$

The selection of compensation components of error amplifier transfer function $\mathrm{G}_{\mathrm{EA}}(\mathrm{s})$ to achieve the desired regulation accuracy, dynamic response and stability margin is explained in detail in Chapter 5.

The small-signal model was verified on Delta power supply DPS-250 AB A using original compensation component values. The calculated Bode plots of control loop $\mathrm{T}_{1}$ are obtained using a MathCad ${ }^{\text {TM }}$ worksheet presented in Appendix B, and measured control loop $\mathrm{T}_{1}$ are shown in Fig. 17. As can be seen, both the measured and calculated gain and phase show an excellent agreement across the frequency range of interest.

Fig. 17 Calculated and measured Bode plots of loop gain $T_{1}$ of Delta power supply DPS250 AB A with original component values.

## 5. DESIGN GUIDELINES

Generally, the self oscillating flyback converter operates in the discontinuous-conduction mode (DCM) but close to the continuous/discontinuous conduction mode (CCM/DCM) boundary, as can be seen from its typical waveforms shown in Fig. 18. The power stage does not operate exactly at the boundary due to a resonance between the output capacitance CoSs of main switch $S_{1}$ with magnetizing inductance $L_{M}$ and a delay time introduced by control circuit components (e.g., $\mathrm{C}_{\mathrm{ZCD}}, \mathrm{R}_{\mathrm{ZCD}}$, and $\mathrm{C}_{\mathrm{ISS}}$ ). Time $\mathrm{t}_{\mathrm{D}}$ between the CCM/DCM boundary and the start of the next switching period $\mathrm{T}_{\mathrm{S}}$, i.e., the DCM time, is nearly constant for a properly designed control

Fig. 18 General power stage waveforms of flyback converter operating at CCM/DCM boundary.
circuit and, can be neglected completely since usually $\mathrm{t}_{\mathrm{D}} \ll \mathrm{T}_{\mathrm{S}}$. As a result, the design of the selfoscillating flyback power stage is the same as the design of the flyback converter operating at the CCM/DCM boundary.

### 5.1. Power Stage Design

To facilitate the design of the power stage, Fig. 19 shows a simplified circuit diagram of the self-oscillating flyback power stage and idealized key waveforms. In addition, the design procedure assumes that the power stage devices are nearly ideal, with the exception of a non-zero forward voltage drop $\mathrm{V}_{\mathrm{F}}$ across output rectifiers $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$.

Since while switch $S_{1}$ is on voltage $V_{I N}$ is applied across magnetizing inductance $L_{M}$ and

Fig. 19 Self-oscillating flyback converter: (a) simplified circuit diagram; (b) key waveforms.
switch current increases linearly, i.e., $i_{S 1}=i_{M}=\frac{V_{I N}}{L_{M}} t$, peak switch current $i_{S 1}^{p k}$ is equal to

$$
\begin{equation*}
\mathrm{i}_{\mathrm{Sl}}^{\mathrm{pk}}=\frac{\mathrm{V}_{\mathrm{IN}}}{\mathrm{~L}_{\mathrm{M}}} \mathrm{DT}_{\mathrm{S}} \tag{5.1}
\end{equation*}
$$

where D is the duty cycle. When switch $\mathrm{S}_{1}$ is off, switch current $\mathrm{i}_{\mathrm{S} 1}=0$ and magnetizing energy discharges through the outputs. From Fig. 19 (b), the peak rectifier currents $i_{1}^{\mathrm{pk}}$ and $\mathrm{i}_{2}^{\mathrm{pk}}$ can be determined as a function of the specified average output currents $I_{1}$ and $I_{2}$, as

$$
\begin{align*}
& \mathrm{I}_{1}=\frac{1}{2} \mathrm{i}_{1}^{\mathrm{pk}}(1-\mathrm{D}) \Rightarrow \mathrm{i}_{1}^{\mathrm{pk}}=\frac{2 \mathrm{I}_{1}}{1-\mathrm{D}},  \tag{5.2}\\
& \mathrm{I}_{2}=\frac{1}{2} \mathrm{i}_{2}^{\mathrm{pk}}(1-\mathrm{D}) \Rightarrow \mathrm{i}_{2}^{\mathrm{pk}}=\frac{2 \mathrm{I}_{2}}{1-\mathrm{D}} . \tag{5.3}
\end{align*}
$$

From the volt-second balance of magnetizing inductance $L_{M}$, the voltage conversion ratio is

$$
\begin{equation*}
\frac{\mathrm{V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}=\frac{\mathrm{D}}{\mathrm{~N}(1-\mathrm{D})} \tag{5.4}
\end{equation*}
$$

where $\mathrm{N}=\mathrm{N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{Sl}}$. Solving Eq. (5.4) for duty cycle D,

$$
\begin{equation*}
\mathrm{D}=\frac{1}{\frac{\mathrm{~V}_{\mathrm{IN}}}{\mathrm{~V}_{\mathrm{O} 1}+\mathrm{V}_{\mathrm{F}}} \frac{\mathrm{~N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}+1} . \tag{5.5}
\end{equation*}
$$

Therefore, $D$ is a function of the input voltage $V_{I N}$, output voltage $V_{O 1}$, turns ratio $N_{S 1} / N_{P}$ and forward voltage drop $\mathrm{V}_{\mathrm{F}}$. The maximum duty cycle $\mathrm{D}^{\text {max }}$, which occurs at low-line $\mathrm{V}_{\mathrm{IN}}^{\mathrm{min}}$ and full load $P_{\mathrm{O}}^{\max }$, is then given by

$$
\begin{equation*}
\mathrm{D}^{\max }=\frac{1}{\frac{\mathrm{~V}_{\mathrm{IN}}^{\min }}{\mathrm{V}_{\mathrm{O} 1}+\mathrm{V}_{\mathrm{F}}} \frac{\mathrm{~N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}+1} \tag{5.6}
\end{equation*}
$$

When output voltage $\mathrm{V}_{\mathrm{O} 1}$ is tightly regulated, output voltage $\mathrm{V}_{\mathrm{O} 2}$ is

$$
\begin{equation*}
\mathrm{V}_{\mathrm{O} 2}=\left(\mathrm{V}_{\mathrm{O} 1}+\mathrm{V}_{\mathrm{F}}\right) \frac{\mathrm{N}_{\mathrm{S} 2}}{\mathrm{~N}_{\mathrm{S} 1}}-\mathrm{V}_{\mathrm{F}}, \tag{5.7}
\end{equation*}
$$

which is considered loosely regulated since forward voltage $\mathrm{V}_{\mathrm{F}}$ changes as a function of output current $i_{1}$ and temperature.

The maximum voltage across main switch $\mathrm{S}_{1}$ during the off time is

$$
\begin{equation*}
\mathrm{V}_{\mathrm{Sl}}^{\mathrm{OFF}}=\mathrm{V}_{\mathrm{IN}}^{\max }+\left(\mathrm{V}_{\mathrm{OI}}+\mathrm{V}_{\mathrm{F}}\right) \frac{\mathrm{N}_{\mathrm{P}}}{\mathrm{~N}_{\mathrm{Sl}}}, \tag{5.8}
\end{equation*}
$$

while the maximum voltage across the output rectifiers $D_{1}$ and $D_{2}$ during the on time is

$$
\begin{gather*}
\mathrm{V}_{\mathrm{D} 1}^{\mathrm{ON}}=\mathrm{V}_{\mathrm{IN}}^{\max } \frac{\mathrm{N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}+\mathrm{V}_{\mathrm{O} 1} \text { and }  \tag{5.9}\\
\mathrm{V}_{\mathrm{D} 2}^{\mathrm{ON}}=\mathrm{V}_{\mathrm{IN}}^{\max } \frac{\mathrm{N}_{\mathrm{S} 2}}{\mathrm{~N}_{\mathrm{P}}}+\mathrm{V}_{\mathrm{O} 2} \tag{5.10}
\end{gather*}
$$

respectively.
The selection of turns ratio $\mathrm{N}_{\mathrm{S} 1} / \mathrm{N}_{\mathrm{P}}$ is based on a design trade-off between the maximum voltage stress across main switch $S_{1}$, which decreases as turns ratio $N_{S 1} / N_{P}$ increases, and the maximum voltage stress across output rectifiers $D_{1}$ and $D_{2}$, which decreases as $N_{S 1} / N_{P}$ decreases, as shown in Eqs. (5.8) and (5.9). The selection of turns ratio $N_{S 2} / N_{P}$ is made once $N$ is selected using Eq. (5.4). Device performance also plays a role in the selection of the transformer turns ratio. For example, it is generally desirable to use a Schottky device as the
output rectifier since it generally has a lower forward voltage drop than a fast-recovery type rectifier, which results in a lower conduction loss of the rectifier. However, the highest available breakdown voltage for a Schottky device is 200 V, which, based on converter specifications, often requires turns ratio $\mathrm{N}_{\mathrm{Sl}} / \mathrm{N}_{\mathrm{P}}$ to be generally low, which increases the voltage stress across main switch $S_{1}$. Generally, the on resistance of a MOSFET device increases as the rated voltage increases, which generally increases the conduction loss of $\mathrm{S}_{1}$.

It should also be noted that the presence of transformer leakage inductance results in an increased voltage stress on all devices as it resonates with circuit parasitic capacitances during the turn-off of switch $S_{1}$. Often a voltage clamp is needed to limit the amplitude of the voltage ringings which results in higher losses as the clamp voltage decreases. This adds another design trade-off on the rated voltage of the device. Finally, a derating factor of $80 \%$ is usually used in the design process, which also affects the selection of the device, the clamp voltage level, and the transformer turns ratio. Therefore, the selection of transformer turns ratio's is often an iterative process, and should be carefully considered by the designer.

The selection of magnetizing inductance $\mathrm{L}_{\mathrm{M}}$ is based on the selection of the minimum switching frequency $\mathrm{f}_{\mathrm{S}}^{\mathrm{min}}$. Namely, from the power balance

$$
\begin{equation*}
\mathrm{P}_{\mathrm{IN}}=\left\langle\mathrm{i}_{\mathrm{IN}}>\mathrm{V}_{\mathrm{IN}}=\frac{1}{2} \mathrm{i}_{\mathrm{Sl}}^{\mathrm{pk}} \mathrm{DV} V_{\mathrm{IN}}=\frac{\mathrm{P}_{\mathrm{O}}}{\eta}\right. \tag{5.11}
\end{equation*}
$$

where $P_{\text {IN }}$ is the input power, $\mathrm{P}_{\mathrm{O}}$ is the output power, $\left\langle\mathrm{i}_{\text {IN }}>\right.$ is the average input current, and $\eta$ is the converter efficiency, it follows that $\mathrm{L}_{\mathrm{M}}$ and $\mathrm{f}_{\mathrm{S}}$ are related as

$$
\begin{equation*}
\mathrm{P}_{\mathrm{O}}=\frac{1}{2} \frac{\mathrm{~V}_{\mathrm{IN}}^{2}}{\mathrm{~L}_{\mathrm{M}}} \frac{\mathrm{D}^{2} \eta}{\mathrm{f}_{\mathrm{S}}} \tag{5.12}
\end{equation*}
$$

Since minimum switching frequency $\mathrm{f}_{\mathrm{S}}^{\min }$ occurs at full power $\mathrm{P}_{\mathrm{O}}^{\max }$ and low line $\mathrm{V}_{\mathrm{IN}}^{\min }$, from Eq. (5.12) the relationship between $\mathrm{P}_{\mathrm{O}}^{\max }$ and $\mathrm{f}_{\mathrm{S}}^{\min }$ is

$$
\begin{equation*}
\mathrm{P}_{\mathrm{O}}^{\max }=\frac{1}{2} \frac{\mathrm{~V}_{\mathrm{IN}}^{\min 2}}{\mathrm{~L}_{\mathrm{M}}} \frac{\mathrm{D}^{\max 2} \eta}{\mathrm{f}_{\mathrm{S}}^{\min }} \tag{5.13}
\end{equation*}
$$

Solving Eq. (5.13), it follows that

$$
\begin{equation*}
\mathrm{L}_{\mathrm{M}}=\frac{1}{2} \frac{\eta \mathrm{~V}_{\mathrm{IN}}^{\min 2} \mathrm{D}^{\max 2}}{\mathrm{P}_{\mathrm{O}}^{\max } \mathrm{f}_{\mathrm{S}}^{\min }} \tag{5.14}
\end{equation*}
$$

Generally, the minimum switching frequency $f_{S}^{m i n}$ is chosen to reduce the maximum switching frequency that occurs at the minimum load and high line. Generally, 20 kHz is the lowest permitted switching frequency since it is the upper threshold of the audible range. However, such a low switching frequency often results in a larger size transformer core. Therefore, the selection of the minimum switching frequency requires a careful consideration of trade-offs between the size and performance of transformer $\mathrm{T}_{1}$.

The selection of output capacitor $\mathrm{C}_{\mathrm{O} 1}$ is generally made based on the output-voltage ripple $\Delta \mathrm{V}_{\mathrm{O}}$ requirements. The output voltage ripple is the sum of voltage $\mathrm{V}_{\mathrm{Rc}}$ and voltage $\mathrm{V}_{\mathrm{C}}$ in quadrature,

$$
\begin{equation*}
\Delta \mathrm{V}_{\mathrm{O}}=\sqrt{\left(\mathrm{V}_{\mathrm{Rc}}\right)^{2}+\left(\mathrm{V}_{\mathrm{C}}\right)^{2}} \tag{5.15}
\end{equation*}
$$

where:

$$
\begin{equation*}
\mathrm{V}_{\mathrm{Rc}}=\mathrm{i}_{1}^{\mathrm{pk}} \mathrm{R}_{\mathrm{CO1}} \tag{5.16}
\end{equation*}
$$

$$
\begin{gather*}
\mathrm{V}_{\mathrm{C}}=\frac{1}{\mathrm{C}_{\mathrm{O} 1}} \int_{0}^{\mathrm{t}_{\mathrm{p}}} \mathrm{i}_{\mathrm{C}} \mathrm{dt}=\frac{1}{2 \mathrm{C}_{\mathrm{O} 1}} \frac{\mathrm{~V}_{\mathrm{Ol}} \mathrm{~N}^{2}}{\mathrm{~L}_{\mathrm{M}}} \mathrm{t}_{\mathrm{P}}^{2},  \tag{5.17}\\
\mathrm{t}_{\mathrm{P}}=\frac{\left(\mathrm{i}_{1}^{\mathrm{pk}}-\mathrm{I}_{\mathrm{O}}\right)}{\mathrm{V}_{\mathrm{O} 1}} \frac{\mathrm{~L}_{\mathrm{M}}}{\mathrm{~N}^{2}} . \tag{5.18}
\end{gather*}
$$

Substituting Eq. (4.16) into Eq. (4.15),

$$
\begin{equation*}
\mathrm{V}_{\mathrm{C}}=\frac{\left(\mathrm{i}_{1}^{\mathrm{pk}}-\mathrm{I}_{\mathrm{O}}\right)^{2}}{2 \mathrm{C}_{\mathrm{Ol}}} \frac{\mathrm{~L}_{\mathrm{M}}}{\mathrm{~V}_{\mathrm{O} 1} \mathrm{~N}^{2}} . \tag{5.19}
\end{equation*}
$$

Generally, $\mathrm{V}_{\mathrm{Rc}} \gg \mathrm{V}_{\mathrm{C}}$ for the boundary operating converter and Eq. (5.15) reduces to $\Delta V_{\mathrm{O}}=\mathrm{V}_{\mathrm{Rc}}$ due to it's high peak winding current $\mathrm{i}_{1}^{\mathrm{pk}}$. For this case, the selection of output capacitor $\mathbf{C}_{\mathbf{O} 1}$ is often made based on resistance $\mathbf{R}_{\mathbf{C O} 1}$, as well as capacitor volume and voltage rating. If the allowed board space is too small for the required output capacitors, a second stage LC filter can be added to further attenuate the output voltage ripple. In addition, it should be noted that $\mathrm{R}_{\mathrm{C}}$ changes as a function of temperature. Therefore, careful consideration of expected component temperature should be included when the output capacitor is selected.

### 5.2. Control Stage Design

The design of the control stage, shown in Fig. 20(a), is also an iterative process consisting of a series of design steps which were developed based on several design constraints. The goal of this design procedure is to ensure stable voltage regulation over the entire line and load range.

### 5.2.1. Steady State Considerations

To achieve good output voltage regulation during steady state operation, the ramp voltage $\mathrm{i}_{\mathrm{S} 1} \mathrm{R}_{\mathrm{S}}$ summed with the DC voltage $\mathrm{i}_{\mathrm{e}}\left(\mathrm{R}_{\mathrm{F}}+\mathrm{R}_{\mathrm{S}}\right)$ must fit within the "regulation window" throughout the line and load range, as illustrated in Fig. 20(b). The upper limit of the regulation window is the threshold voltage $\mathrm{V}_{\gamma}$ of transistor $\mathrm{Q}_{1}$, which is inherent to the transistor selected, whereas the lower limit of the regulation window is defined by the full load current. To achieve output voltage regulation, resistors $R_{B}, R_{S}$, and $R_{F}$ must be carefully selected to limit the error current within the regulation window.

The maximum error current occurs at minimum load, as shown in Fig. 20(b). At minimum load, less energy is needed to maintain the output voltage which is why the on time of switch $\mathrm{S}_{1}$ is very short. Conversely, the minimum error current occurs at full load, as shown in Fig. 20(b), because a longer on time is needed to store the required energy. It should be noted that the duty cycle is still independent from the load since a proportional change in the on time $\mathrm{t}_{\mathrm{ON}}$ results in a proportional change in the switching period $\mathrm{T}_{\mathrm{S}}$, and an inverse proportional change in the switching frequency $\mathrm{f}_{\mathrm{S}}$. It should also be noted that unlike the standard PWM, whose on time is determined at the moment the ramp voltage reaches the control voltage, the on time of this control circuit is determined once sufficient charge is removed from input capacitance $\mathrm{C}_{\text {ISS }}$ by transistor $\mathrm{Q}_{1}$. Transistor $\mathrm{Q}_{1}$ is turned on at the moment that base voltage $\mathrm{V}_{\mathrm{Qbe}}$ reaches its threshold voltage $\mathrm{V}_{\gamma}$.

The design constraints for the selection of the control circuit components for steady state operation are based on the operating range of the circuit as well as on component ratings. Specifically, the cathode-anode voltage $\mathrm{V}_{\mathrm{KA}}$ and cathode current $\mathrm{I}_{\mathrm{K}}$ of error amplifier TL431 are limited to

Fig. 20 Self-oscillating flyback converter: (a) Equivalent control stage schematic of circuit operating at steady state, (b) key control circuit waveforms at minimum and maximum load current.

$$
\begin{gather*}
\mathrm{V}_{\mathrm{REF}}<\mathrm{V}_{\mathrm{KA}}<36 \mathrm{~V}  \tag{5.20}\\
1 \mathrm{~mA}<\mathrm{I}_{\mathrm{K}}<100 \mathrm{~mA}
\end{gather*}
$$

From Fig. 20, $\mathrm{V}_{\mathrm{KA}}$ can be expressed as,

$$
\begin{equation*}
\mathrm{V}_{\mathrm{KA}}=\mathrm{V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{d}}-\mathrm{I}_{\mathrm{K}} \mathrm{R}_{\mathrm{B}} \tag{5.21}
\end{equation*}
$$

Since at minimum load, current $\mathrm{I}_{\mathrm{K}}$ is maximum, as seen from Fig. 20, and voltage $\mathrm{V}_{\mathrm{KA}}$ is minimum, resistor $R_{B}$ is determined from

$$
\begin{equation*}
\mathrm{R}_{\mathrm{B}}<\frac{\mathrm{V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{d}}-\mathrm{V}_{\mathrm{KA}}^{\min }}{\mathrm{I}_{\mathrm{K}}^{\max }} \tag{5.22}
\end{equation*}
$$

The selection of sense resistor $\mathrm{R}_{\mathrm{S}}$ is limited by its maximum power dissipation. If maximum power dissipation $\mathrm{P}_{\mathrm{RS}}$ of resistor $\mathrm{R}_{\mathrm{S}}$ is limited to below $0.1 \%$ of maximum input power, than resistor $\mathrm{R}_{\mathrm{S}}$ is given by

$$
\begin{equation*}
\mathrm{P}_{\mathrm{RS}} \approx(0.1 \%) \mathrm{P}_{\mathrm{IN}}^{\max } \Rightarrow \mathrm{R}_{\mathrm{S}}=\frac{(0.1 \%) \mathrm{P}_{\mathrm{IN}}^{\max }}{\left(\mathrm{i}_{\mathrm{Sk}}^{\mathrm{pk}} \sqrt{\mathrm{D}^{\max } / 3}\right)^{2}} \tag{5.23}
\end{equation*}
$$

The selection of resistor $\mathrm{R}_{\mathrm{F}}$ is limited at minimum load by maximum error current $\mathrm{i}_{\mathrm{e}}^{\max }$, sense resistor $\mathrm{R}_{\mathrm{S}}$, and cut-off voltage $\mathrm{V}_{\gamma}$,

$$
\begin{equation*}
\mathrm{i}_{\mathrm{e}}^{\max }\left(\mathrm{R}_{\mathrm{F}}+\mathrm{R}_{\mathrm{S}}\right) \leq \mathrm{V}_{\gamma}, \tag{5.24}
\end{equation*}
$$

where $\mathrm{R}_{\mathrm{F}}$ must be much greater than $\mathrm{R}_{\mathrm{S}}$. At full load, the selection of resistors $\mathrm{R}_{\mathrm{F}}$ and $\mathrm{R}_{\mathrm{S}}$ are further limited by the minimum error current $\mathrm{i}_{\mathrm{e}}^{\min }$ and the maximum switch current $\mathrm{i}_{\mathrm{S} 1}^{\mathrm{pk}}$,

$$
\begin{equation*}
\mathrm{i}_{\mathrm{e}}^{\min }\left(\mathrm{R}_{\mathrm{F}}+\mathrm{R}_{\mathrm{S}}\right)+\mathrm{i}_{\mathrm{Sl}}^{\mathrm{pk}(\max )} \mathrm{R}_{\mathrm{S}}>\mathrm{V}_{\gamma} \tag{5.25}
\end{equation*}
$$

where: $\mathrm{i}_{\mathrm{Sl}}^{\mathrm{pk}(\max )}=\mathrm{V}_{\mathrm{IN}}^{\max } \mathrm{D}^{\max } /\left(\mathrm{L}_{\mathrm{M}} \mathrm{f}_{\mathrm{S}}^{\min }\right)$.
Finally, error current $\mathrm{i}_{\mathrm{e}}$ is related to cathode current $\mathrm{I}_{\mathrm{K}}$ through dc current transfer ratio $\beta$ of optocoupler $\mathrm{IC}_{1}$,

$$
\begin{equation*}
\mathrm{i}_{\mathrm{e}}=\beta \mathrm{I}_{\mathrm{K}} \tag{5.26}
\end{equation*}
$$

The design procedure for the selection of the control circuit components $R_{F}, R_{S}$, and $R_{B}$ for steady state operation begins with the selection of the maximum cathode current $I_{\mathrm{K}}^{\max }$ using the device ratings for error amplifier TL431.
$\underline{\text { STEP } 1} \quad$ Choose $\mathrm{I}_{\mathrm{K}}^{\max }$ based on constraint (5.20).
$\underline{\text { STEP } 2} \quad$ Determine $i_{\mathrm{e}}^{\max }$ from constraint (5.26).
$\underline{\text { STEP } 3}$ Determine resistor $\mathrm{R}_{\mathrm{S}}$ from constraint (5.23).
$\underline{\text { STEP } 4}$ Determine resistor $\mathrm{R}_{\mathrm{F}}$ from constraint (5.24).

STEP 5
Determine resistor $\mathrm{R}_{\mathrm{B}}$ from constraint (5.22).

It should be noted that resistor $R_{B}$, whose value also affects the voltage loop dc gain, should be chosen as low as possible while still adhering to STEP 5 in order to maximize the loop gain. Generally, a $20 \Omega$ resistor serves as a good first iteration for output voltage $\mathrm{V}_{\mathrm{Ol}}$ less than 35 V . Later, when system stability is considered, the value of resistor $\mathrm{R}_{\mathrm{B}}$ will be re-evaluated.

Determine $\mathrm{I}_{\mathrm{K}}^{\mathrm{min}}$ from constraint (5.25). Check result against constraint (5.22).

STEP 7
Check $\mathrm{V}_{\mathrm{KA}}^{\max }$ using Eq. (5.21) at the maximum load condition (i.e., minimum cathode current $\mathrm{i}_{\mathrm{K}}^{\min }$ ).

Following STEPS 1-7 will ensure that the control circuit operates within the regulation window. However, the calculated values are only a starting point and are still subject to further optimization at the hardware level.

The design of components $\mathrm{R}_{\mathrm{A}}, \mathrm{C}_{\mathrm{ZCD}}, \mathrm{R}_{\mathrm{ZCD}}, \mathrm{ZD}_{1}$, and $\mathrm{R}_{\mathrm{ST}}$ can be determined independently from STEPS 1-7 once all the constraints are satisfied. For example, the role of resistor $R_{A}$ is to reduce the power loss of the phototransistor within optocoupler $\mathrm{IC}_{1}$ by developing a maximum voltage across it equal to $i_{\mathrm{e}}^{\max } \mathrm{R}_{\mathrm{A}}$. The power dissipated by the phototransistor, which is limited by the device manufacturer, is then

$$
\left.\underline{\text { STEP 8 }} \quad \mathrm{P}_{\mathrm{IC1}}=\mathrm{V}_{\mathrm{CE}} \mathrm{i}_{\mathrm{e}}^{\max }=\left(\mathrm{V}_{\mathrm{O} 2}-\mathrm{i}_{\mathrm{e}}^{\max } \mathrm{R}_{\mathrm{A}}-\mathrm{V}_{\mathrm{Qbe}}\right)\right)_{\mathrm{e}}^{\max }<\text { device power rating } .
$$

The role of capacitor $\mathrm{C}_{\mathrm{ZCD}}$ is to block DC current during start-up, allowing charge to be delivered from the input voltage through resistor $\mathrm{R}_{\mathrm{ST}}$ until switch $\mathrm{S}_{1}$ turns on for the first time. Otherwise, capacitor $\mathrm{C}_{\mathrm{ZCD}}$ merely delays the full turn on of switch $\mathrm{S}_{1}$ by increasing the length of time spent in the constant-current region, which is undesirable from a power conversion efficiency point of view. Therefore, it is recommended that $\mathrm{C}_{\text {ZCD }}$ be set ten times greater than input capacitance $\mathrm{C}_{\text {ISS. }}$. Since $\mathrm{C}_{\mathrm{ZCD}}$ and $\mathrm{C}_{\mathrm{ISS}}$ form a voltage divider at the gate of $\mathrm{S}_{1}$, steps should
be taken to clamp the gate voltage $\mathrm{V}_{\mathrm{G}}$ with a zener clamp $\mathrm{ZD}_{1}$, to avoid exceeding the terminal voltage rating. This zener breakdown voltage should be set as per the device rating.

## STEP 9 $\quad$ Select $C_{Z C D}=10 \mathrm{xC}_{\text {ISS }}$.

The role of resistor $\mathrm{R}_{\mathrm{ZCD}}$ is to limit the power dissipated by zener clamp $\mathrm{ZD}_{1}$. Therefore,

STEP 10

$$
\text { Select } \mathrm{R}_{\mathrm{ZCD}}=\frac{\mathrm{V}_{\mathrm{IN}}^{\max } \frac{\mathrm{N}_{\mathrm{S} 2}}{\mathrm{~N}_{\mathrm{P}}}-\mathrm{V}_{\mathrm{ZD} 1}}{\mathrm{P}_{\mathrm{ZD} 1}} \mathrm{~V}_{\mathrm{ZD} 1}
$$

where $\mathrm{P}_{\mathrm{ZD} 1}<80 \%$ of maximum specified power rating of $\mathrm{ZD}_{1}$.
Start-up resistor $\mathrm{R}_{\mathrm{ST}}$ should be chosen based on the maximum start-up time of the converter while limiting its maximum power dissipation. Generally,

STEP 11

$$
\text { Select } \mathrm{R}_{\mathrm{ST}} \approx \frac{\mathrm{~V}_{\mathrm{IN}}^{\max ^{2}}}{\mathrm{P}_{\mathrm{ST}}}
$$

where $\mathrm{P}_{\mathrm{ST}} \approx(1 \%) \mathrm{P}_{\mathrm{O}}$, though its actual value is generally not critical.

Finally, resistors $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ divide down output voltage $\mathrm{V}_{\mathrm{O} 1}$ to be compared to reference voltage $\mathrm{V}_{\text {REF }}$ which is internal to error amplifier TL431. Therefore,

STEP 12

$$
\text { Select } R_{1}=\frac{R_{2}}{\frac{\mathrm{~V}_{\mathrm{O} 1}}{\mathrm{~V}_{\mathrm{REF}}}-1} .
$$

### 5.1.2. Compensation Calculations

The compensation components $\mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}$, and $\mathrm{R}_{\mathrm{EA} 1}$ of the error amplifier are determined so that the control loop achieves the desired regulation accuracy and dynamic response of the
output voltage while maintaining an acceptable phase margin (typically $>45^{\circ}$ ) in the entire line and load range. Generally, a good regulation accuracy and fast transient response requires that closed loop $\mathrm{T}_{1}$ has a high dc gain and high bandwidth. Typically, a dc gain of 20 to 60 dB is sufficient for good regulation accuracy, whereas crossover ferquency $f_{C}$ less than one-fourth of $\mathrm{f}_{\mathrm{S}}^{\min }$, i.e., $\mathrm{f}_{\mathrm{C}}<\mathrm{f}_{\mathrm{S}}^{\min } / 4$, is usually designed for.

Figure 21 shows the gain Bode plot of transfer function $G_{V_{E A V O}}(s)$ (shown previously in Fig. 16), the desired closed loop gain $T_{1}$, and the gain plot of compensated error amplifier $\mathrm{G}_{\mathrm{EA}}(\mathrm{s})$ which produces desired closed loop gain $\mathrm{T}_{1}$. As can be seen from Fig. 21, the optimum compensation of the error amplifier has 2 poles and 1 zero, i.e., the error amplifier transfer function can be expressed as

$$
\begin{equation*}
\mathrm{G}_{\mathrm{EA}}(\mathrm{~s})=\frac{\mathrm{A}}{\mathrm{~s}} \cdot \frac{\mathrm{~s} / \mathrm{s}_{\mathrm{zcompl}}+1}{\mathrm{~s} / \mathrm{s}_{\mathrm{pcomp} 2}+1}, \tag{5.27}
\end{equation*}
$$

where A is the gain of the integrator, $\mathrm{s}_{\mathrm{zcomp1}}$ is the compensation zero, and $\mathrm{s}_{\mathrm{pcomp} 2}$ is the second compensation pole.

The integrator in the error amplifier transfer function is used to increase the lowfrequency gain of closed loop gain $T_{1}$, whereas high frequency pole $\mathrm{S}_{\text {pcomp } 2}$ is introduced above the cross-over frequency $\mathrm{f}_{\mathrm{C}}$ (at least 2 octaves above $\mathrm{f}_{\mathrm{C}}$ ) of loop $\mathrm{T}_{1}$ to sufficiently attenuate the gain of $T_{1}$ at the switching frequency to achieve noise immunity of the loop. The compensation zero $s_{\text {zcomp1 }}$ of the error amplifier is placed at pole $f_{p 1}^{*}$ of transfer function $G_{V_{E A V o}}(s)$.

Error amplifier transfer function $\mathrm{G}_{\mathrm{EA}}(\mathrm{s})$ can be realized with capacitors $\mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}$, and resistor $\mathrm{R}_{\mathrm{EA} 1}$ arranged around TL431 IC circuit, as shown in Fig. 13. For the implementation of the error amplifier shown in Fig. 13,

Fig. 21 Gain plots of transfer function $G_{V_{E A V O}}(\mathrm{~s})$, optimum compensation $\mathrm{G}_{\mathrm{EA}}(\mathrm{s})$, and openloop transfer function at breakpoint $\mathrm{T}_{1}$.

$$
\begin{gather*}
\mathrm{A}=\frac{1}{\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}},  \tag{5.28}\\
\mathrm{~s}_{\mathrm{zcompl}}=\frac{1}{\mathrm{R}_{\mathrm{EA} 1} \mathrm{C}_{\mathrm{EA} 1}},  \tag{5.29}\\
\mathrm{~s}_{\mathrm{pcomp} 2}=\frac{1}{\mathrm{R}_{\mathrm{EA} 1}} \cdot\left(\frac{1}{\mathrm{C}_{\mathrm{EA} 1}}+\frac{1}{\mathrm{C}_{\mathrm{EA} 2}}\right) \tag{5.30}
\end{gather*}
$$

For a desired crossover frequency $f_{C}$ of loop $T_{1}$ and pole frequency $f_{p 1}^{*}$ of transfer function $G_{E A}(s)$, ans the selection of $f_{\text {zcomp1 }}$ and $f_{\text {pcomp2 }}$ so that

$$
\begin{gather*}
\mathrm{f}_{\mathrm{zcomp1}}=\mathrm{f}_{\mathrm{pl}}^{*}  \tag{5.31}\\
\mathrm{f}_{\text {pcomp } 2}>4 \mathrm{f}_{\mathrm{C}} \tag{5.32}
\end{gather*}
$$

the compensation components $\mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}$, and $\mathrm{R}_{\mathrm{EA} 1}$ can be calculated from Eqns. (C.33) - (C.35) as derived in Appendix C.

$$
\begin{gather*}
\mathrm{C}_{\mathrm{EA} 1}=\frac{.73}{2 \pi \mathrm{f}_{\mathrm{C}} \mathrm{R}_{\mathrm{d} 1}}  \tag{5.33}\\
\mathrm{R}_{\mathrm{EA} 1}=\frac{1}{\mathrm{~s}_{\mathrm{p} 1}^{*}} \cdot \frac{1}{\mathrm{C}_{\mathrm{EA} 1}}  \tag{5.34}\\
\mathrm{C}_{\mathrm{EA} 2}=\frac{\mathrm{C}_{\mathrm{EA} 1}}{10} \tag{5.35}
\end{gather*}
$$

## 6. DESIGN EXAMPLE

A design example is presented of a $16 \mathrm{~V} / 1$ A converter operating with a dc input voltage range $255<\mathrm{V}_{\text {IN }}<373$, an output power range $10 \%<\mathrm{Po}<100 \%$, and an output voltage ripple of $1 \%$, using the proposed design procedure.

The design of the power stage begins with the selection of main switch $\mathrm{S}_{1}$. A 600 V MOSFET device is chosen based on design experience. Assuming $83 \%$ derating of the main switch, the maximum voltage across the drain-source is 500 V . The turns ratio $\mathrm{N}_{\mathrm{P}} / \mathrm{N}_{\mathrm{S} 1}$ is next chosen using Eq. (5.8),

$$
\begin{equation*}
\frac{\mathrm{N}_{\mathrm{P}}}{\mathrm{~N}_{\mathrm{S} 1}}=\frac{\mathrm{V}_{\mathrm{S} 1}^{\mathrm{OFF}}-\mathrm{V}_{\mathrm{IN}}^{\max }}{\mathrm{V}_{\mathrm{O} 1}+\mathrm{V}_{\mathrm{F}}}=\frac{500-373}{16+0.8} \approx 7.56 \tag{6.1}
\end{equation*}
$$

The resulting reverse voltage across rectifier $\mathrm{D}_{1}$ is then determined using Eq. (5.9),

$$
\begin{equation*}
\mathrm{V}_{\mathrm{D} 1}^{\mathrm{ON}}=\mathrm{V}_{\mathrm{IN}}^{\max } \frac{\mathrm{N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}+\mathrm{V}_{\mathrm{O} 1}=373 \cdot \frac{1}{7.56}+16 \approx 65 \mathrm{~V} \tag{6.2}
\end{equation*}
$$

When $80 \%$ derating is observed, the rating of the rectifier should be at least 80 V . A 100 V rectifier is chosen as the closest standard value. The maximum duty cycle is then determined from Eq. (5.6),

$$
\begin{equation*}
\mathrm{D}^{\max }=\frac{1}{\frac{\mathrm{~V}_{\mathrm{IN}}^{\min }}{\mathrm{V}_{\mathrm{O} 1}+\mathrm{V}_{\mathrm{F}}} \frac{\mathrm{~N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}+1}=\frac{1}{\frac{255}{16+0.8} \frac{1}{7.56}+1} \approx 0.332 . \tag{6.3}
\end{equation*}
$$

Next, minimum switching frequency $\mathrm{f}_{\mathrm{S}}^{\mathrm{min}}$ is chosen as 40 kHz which occurs at minimum input voltage $V_{I N}^{m i n}$ operating at full load $\mathrm{P}_{\mathrm{O}}^{\max }$. Magnetizing inductance $\mathrm{L}_{\mathrm{M}}$ is then chosen using Eq. (5.14) assuming 70 \% overall efficiency,

$$
\begin{equation*}
\mathrm{L}_{\mathrm{M}}=\frac{1}{2} \frac{\eta \mathrm{~V}_{\mathrm{IN}}^{\min ^{2}} \mathrm{D}^{\max ^{2}}}{\mathrm{P}_{\mathrm{O}}^{\max } \mathrm{f}_{\mathrm{S}}^{\min }}=\frac{1}{2} \frac{(0.7)(255)^{2}(0.332)^{2}}{(16)(40 \mathrm{k})} \approx 3.9 \mathrm{mH} \tag{6.4}
\end{equation*}
$$

The maximum peak output current $i_{1}^{p k}$ is then calculated using Eq. (5.2) for $D=D^{\max }$,

$$
\begin{equation*}
\mathrm{i}_{1}^{\mathrm{pk}}=\frac{2 \mathrm{I}_{1}}{1-\mathrm{D}^{\max }}=\frac{2 \cdot 1}{1-0.332} \approx 3 \mathrm{~A} . \tag{6.5}
\end{equation*}
$$

The output capacitor $\mathrm{C}_{\mathrm{O} 1}$ is determined based on the $1 \%$ output voltage ripple requirement. When it is assumed that peak-to-peak capacitor voltage $\mathrm{V}_{\mathrm{C}}$ is much less than peak-to-peak resistor voltage $\mathrm{V}_{\mathrm{Rc}}$, i.e., $\mathrm{V}_{\mathrm{C}} \ll \mathrm{V}_{\mathrm{Rc}}$, Eq. (5.15) reduces to $\Delta \mathrm{V}_{\mathrm{O}} \approx \mathrm{V}_{\mathrm{Rc}}$. Solving for equivalent series resistance $\mathrm{R}_{\mathrm{CO}}$,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{CO} 1}=\frac{\Delta \mathrm{V}_{\mathrm{O}}}{\mathrm{i}_{1}^{\mathrm{pk}}}=\frac{(0.01)(16)}{3} \approx 0.053 \Omega . \tag{6.6}
\end{equation*}
$$

The factors under consideration for the selection of the output capacitance is then based on the calculated value of equivalent series resistance $\mathrm{R}_{\mathrm{CO}}$, as well as capacitor volume and voltage rating. The capacitance selected, based on manufacturer's datasheet and calculated equivalent series resistance $\mathrm{R}_{\mathrm{CO}}$, is

$$
\begin{equation*}
\mathrm{C}_{\mathrm{Ol}}=220 \mu \mathrm{~F} . \tag{6.7}
\end{equation*}
$$

In addition, to further attenuate the switching ripple a second stage LC filter is added whose values are $\mathrm{L}_{\mathrm{F}}=12 \mu \mathrm{H}, \mathrm{C}_{\mathrm{F}}=470 \mu \mathrm{~F}$, and equivalent series resistance $\mathrm{R}_{\mathrm{LF}}=42 \mathrm{~m} \Omega$ and $\mathrm{R}_{\mathrm{CF}}=0.19 \mathrm{~m} \Omega$, respectively.

Finally, for simplicity, the turns ratio from primary winding $\mathrm{N}_{\mathrm{P}}$ to auxiliary winding $\mathrm{N}_{\mathrm{S} 2}$ is chosen as

$$
\begin{equation*}
\frac{\mathrm{N}_{\mathrm{P}}}{\mathrm{~N}_{\mathrm{S} 2}}=\frac{\mathrm{N}_{\mathrm{P}}}{\mathrm{~N}_{\mathrm{S} 1}}=7.56 \tag{6.8}
\end{equation*}
$$

The design of the control stage follows the aforementioned design procedure. It begins with STEP 1, the selection of maximum cathode current $\mathrm{I}_{\mathrm{K}}^{\max }$,

$$
\begin{equation*}
\mathrm{I}_{\mathrm{K}}^{\max }=20 \mathrm{~mA} \tag{6.9}
\end{equation*}
$$

From STEP 2, the maximum error current which is reflected through the opto-coupler is then

$$
\begin{equation*}
\mathrm{i}_{\mathrm{e}}^{\max }=\beta \mathrm{I}_{\mathrm{K}}^{\max }=(0.8)(20)=16 \mathrm{~mA}, \tag{6.10}
\end{equation*}
$$

for dc current transfer ratio $\beta=0.8$.

The selection of the sensing resistor $\mathrm{R}_{\mathrm{S}}$ is made next based on it's maximum power dissipation, as discussed in STEP 3,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{S}}=\frac{\mathrm{P}_{\mathrm{RS}}^{\max }}{\left[\mathrm{i}_{\mathrm{S}}^{\mathrm{pk}} \sqrt{\frac{\mathrm{D}^{\max }}{3}}\right]^{2}}=\frac{(0.001)(16)}{(0.39)^{2}\left(\sqrt{\frac{0.332}{3}}\right)^{2}} \approx 1 \Omega \tag{6.11}
\end{equation*}
$$

where $\mathrm{i}_{\mathrm{Sl}}^{\mathrm{pk}}=\mathrm{i}_{1}^{\mathrm{pk}} \frac{\mathrm{N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}=\frac{2 \mathrm{I}_{1}}{1-\mathrm{D}^{\max }} \frac{\mathrm{N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}=(3)\left(\frac{1}{7.56}\right) \approx 0.396 \mathrm{~A}$

The selection of resistor $R_{F}$ is made next using STEP 4 and the selected value of $R_{S}$,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{F}}=\frac{\mathrm{V}_{\gamma}}{\mathrm{i}_{\mathrm{e}}^{\max }}-\mathrm{R}_{\mathrm{S}}=\frac{0.6}{16 \mathrm{~m}}-1 \approx 37 \Omega \tag{6.12}
\end{equation*}
$$

Using the selected value of $\mathrm{I}_{\mathrm{K}}^{\max }$ and knowing that the forward voltage drop $\mathrm{V}_{\mathrm{d}}$ of the photodiode is 1 V and that the reference voltage $\mathrm{V}_{\text {REF }}$ within error amplifier TL431 is $\mathrm{V}_{\text {REF }}=2.5$ V , STEP 5 is performed,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{B}}<\frac{\mathrm{V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{d}}-\mathrm{V}_{\mathrm{REF}}}{\mathrm{I}_{\mathrm{K}}^{\max }}=\frac{16-1-2.5}{20 \mathrm{~m}}=625 \Omega . \tag{6.13}
\end{equation*}
$$

Therefore, it is necessary that $R_{B}$ be less than $625 \Omega$. However, since the output voltage is much less than 35 V (the maximum rating of TL431), it is desirable to have a low value of $\mathrm{R}_{\mathrm{B}}$ to maximize the dc gain of the voltage loop. Therefore, choose resistor $\mathbf{R}_{\mathbf{B}}=20 \Omega$ as a first iteration. Later when system dynamics are considered, resistor $\mathrm{R}_{\mathrm{B}}$ will be re-evaluated.

STEP 6 ensures that $I_{K}^{\min }$ is greater than the minimum recommended current of device TL431,

$$
\begin{equation*}
\mathrm{I}_{\mathrm{K}}^{\min }=\frac{\mathrm{i}_{\mathrm{e}}^{\mathrm{min}}}{\beta}=\frac{\mathrm{V}_{\gamma}-\mathrm{i}_{\mathrm{Sl}}^{\mathrm{pk}} \mathrm{R}_{\mathrm{S}}}{\beta\left(\mathrm{R}_{\mathrm{F}}+\mathrm{R}_{\mathrm{S}}\right)}=\frac{0.6-(0.396)(1)}{0.8(37+1)} \approx 6.7 \mathrm{~mA} \tag{6.14}
\end{equation*}
$$

$\underline{\text { STEP } 7}$ ensures that $\mathrm{V}_{\mathrm{K}}^{\max }$ is below its maximum device rating,

$$
\begin{equation*}
\mathrm{V}_{\mathrm{K}}^{\max }=-\mathrm{R}_{\mathrm{B}} \mathrm{I}_{\mathrm{K}}^{\min }+\mathrm{V}_{\mathrm{O}}-\mathrm{V}_{\mathrm{d}}=(-20)(6.7 \mathrm{~m})+16-1 \approx 15 \mathrm{~V}<35 \mathrm{~V} \tag{6.15}
\end{equation*}
$$

It is desirable to have the maximum power dissipation of the optocoupler to be below 0.125 W . Therefore, according to STEP 8, resistor $\mathrm{R}_{\mathrm{A}}$ must be at least

$$
\begin{equation*}
\mathrm{R}_{\mathrm{A}}=\frac{-\frac{\mathrm{P}_{\mathrm{ICl}}}{\mathrm{i}_{\mathrm{e}}^{\max }}+\mathrm{V}_{\mathrm{O} 2}-\mathrm{V}_{\gamma}}{\mathrm{i}_{\mathrm{e}}^{\max }}=\frac{-\frac{0.125}{16 \mathrm{~m}}+16-0.6}{16 \mathrm{~m}} \approx 474 \Omega \tag{6.16}
\end{equation*}
$$

Based on this value, resistor $R_{A}$ is selected as $\mathbf{R}_{\mathbf{A}}=\mathbf{1} \mathbf{k} \boldsymbol{\Omega}$.

The MOSFET device selected as main switch $\mathrm{S}_{1}$ is MOTOROLA device MTP1N60E. It has an input capacitance $\mathrm{C}_{\mathrm{ISS}}=310 \mathrm{pF}$. Based on this, capacitor $\mathrm{C}_{\mathrm{ZCD}}$ is selected according to STEP 9,

$$
\begin{equation*}
\mathrm{C}_{\mathrm{ZCD}}=10 \cdot \mathrm{C}_{\mathrm{ISS}} \approx 3.3 \mathrm{nF} \tag{6.17}
\end{equation*}
$$

The zener clamp reverse breakdown voltage should be maximized as permitted by the main switch device. For this design, $\mathrm{V}_{\mathrm{ZD} 1}$ is chosen to be 18 V . The purpose of resistor $\mathrm{R}_{\mathrm{ZCD}}$ is to limit the power dissipated by $\mathrm{ZD}_{1}$, which, for this design, should be no more than 0.125 W . Using STEP 10,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{ZCD}}=\frac{\mathrm{V}_{\mathrm{IN}}^{\max } \frac{\mathrm{N}_{\mathrm{S} 1}}{\mathrm{~N}_{\mathrm{P}}}-\mathrm{V}_{\mathrm{ZD} 1}}{\mathrm{P}_{\mathrm{ZD} 1}} \mathrm{~V}_{\mathrm{ZD1}}=\frac{(373)\left(\frac{1}{7.56}\right)-18}{0.125} \cdot 18 \approx 4.5 \mathrm{k} \Omega \tag{6.18}
\end{equation*}
$$

The selection of start-up resistor $\mathrm{R}_{\mathrm{ST}}$ is also based on maximum power dissipation. Using STEP 11,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{ST}} \approx \frac{\left(\mathrm{~V}_{\mathrm{IN}}^{\mathrm{MAX}}\right)^{2}}{\mathrm{P}_{\mathrm{ST}}}=\frac{(373)^{2}}{0.125} \approx 1.2 \mathrm{MEG} \Omega . \tag{6.19}
\end{equation*}
$$

Finally, the selection of output voltage sensing resistors $\mathrm{R}_{\mathrm{d} 1}$ and $\mathrm{R}_{\mathrm{d} 2}$ is made using STEP 12,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{d} 2}=\frac{\mathrm{R}_{\mathrm{d} 1}}{\frac{\mathrm{~V}_{\mathrm{O} 1}}{\mathrm{~V}_{\mathrm{REF}}}-1} \tag{6.20}
\end{equation*}
$$

Setting $\mathrm{R}_{\mathrm{d} 1}=5.1 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{d} 2}$ is then equal to $940 \Omega$.
The design of circuit compensation relies upon the pole and zero positions of transfer function $\mathrm{G}_{\mathrm{V}_{\mathrm{EA}} \mathrm{Vo}}(\mathrm{s})$ from Eq. (4.17), as shown in Fig. 22. The design guidelines, summarized in Eqs. (5.31) and (5.32), are written for a system whose inner loop $\mathrm{T}_{\text {INNER }}$ has shifted only the pole $\mathrm{s}_{\mathrm{p} 1}$. To ensure that the remaining poles and zeroes are above unity gain of $\mathrm{T}_{\text {INNER }}$, resistor $\mathrm{R}_{\mathrm{B}}$ is adjusted within the limits $20 \leq \mathrm{R}_{\mathrm{B}} \leq 625 \Omega$ using the MathCad worksheet provided in Appendix B, and the optimum value of resistor $\mathbf{R}_{\mathbf{B}}=\mathbf{2 0 0} \boldsymbol{\Omega}$, as shown in MathCad Fig. 23.

The compensation component values are then calculated from Eqs. (5.33) to (5.35) based on pole $\mathrm{s}_{\mathrm{pl}}^{*}$ of transfer function $\mathrm{G}_{\mathrm{VEA}}(\mathrm{s})$ and a desired crossover frequency $\mathrm{f}_{\mathrm{C}}=1 \mathrm{kHz}$,

$$
\begin{gather*}
\mathrm{C}_{\mathrm{EA} 1}=\frac{0.73}{2 \pi \mathrm{f}_{\mathrm{C}} \mathrm{R}_{\mathrm{d} 1}}=\frac{0.73}{2 \pi(1 \mathrm{~K})(5.1 \mathrm{~K})} \approx 22 \mathrm{nF},  \tag{6.21}\\
\mathrm{R}_{\mathrm{EA} 1}=\frac{1}{\mathrm{~s}_{\mathrm{p} 1}^{*}} \cdot \frac{1}{\mathrm{C}_{\mathrm{EA} 1}}=\frac{1}{180} \cdot \frac{1}{22 \mathrm{n}} \approx 39 \mathrm{~K} \Omega  \tag{6.22}\\
\mathrm{C}_{\mathrm{EA} 2}=\frac{\mathrm{C}_{\mathrm{EA} 1}}{10}=\frac{22 \mathrm{n}}{10}=2.2 \mathrm{nF} \tag{6.23}
\end{gather*}
$$

The Bode plot of loop $T_{1}$ using the calculated compensation component values is shown in Fig. 24.

The calculated values are incorporated into the simulation model, shown in Fig. 25, and the simulation is evaluated at minimum input voltage ( 255 V dc), full load ( 1 A ) condition and maximum input ( 373 V dc ), minimum load condition $(0.1 \mathrm{~A}$ ), with comparitive results shown in

Fig. 26. It should be noted that the comparison axis have the same limits in order to make a clear, visual comparison.

## APPENDIX C

Transfer Function Block Derivations

## C. 1 Error-Voltage to Output-Voltage Transfer Function $G_{V e V o}(s)=\hat{V}_{\mathrm{O}} / \hat{\mathrm{V}}_{\mathrm{e}}$

The power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$ is actually the product of two transfer functions

$$
\begin{equation*}
\mathrm{G}_{\mathrm{VeVo}}(\mathrm{~s})=\frac{\hat{\mathrm{V}}_{\mathrm{O}}}{\hat{\mathrm{~V}}_{\mathrm{e}}}=\frac{\hat{\mathrm{I}}_{1}}{\hat{\mathrm{~V}}_{\mathrm{e}}} \frac{\hat{\mathrm{~V}}_{\mathrm{O}}}{\hat{\mathrm{I}}_{1}} \tag{C.1}
\end{equation*}
$$

where $\hat{\mathrm{I}}_{1}$ is the small signal change in the average current of winding $\mathrm{N}_{\mathrm{S} 1}$. By deriving each transfer function independently, the overall power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$ is obtained.

## C.1.1 Error-voltage-to-average output current transfer function $\hat{\mathrm{I}}_{1} / \hat{\mathrm{V}}_{\mathrm{e}}$

To facilitate the derivation of transfer function error voltage $\hat{V}_{\mathrm{e}}$ to average output current
$\hat{I}_{1}$, Fig. C.1. represents the control plant. The output of the plant is average output current $\mathrm{I}_{1}$, and the inputs of the plant include error voltage $\mathrm{V}_{\mathrm{e}}$, input voltage $\mathrm{V}_{\mathrm{IN}}$, and output voltage $\mathrm{V}_{\mathrm{O}}$. From Fig. C.1, the output of the control plant is expressed as a function of its inputs,

$$
\begin{equation*}
\hat{\mathrm{I}}_{1}=\mathrm{I}_{1}\left(\mathrm{~V}_{\mathrm{e}}, \mathrm{~V}_{\mathrm{IN}}, \mathrm{~V}_{\mathrm{O}}\right)=\mathrm{K}_{\mathrm{e}} \hat{\mathrm{~V}}_{\mathrm{e}}+\mathrm{K}_{\mathrm{f}} \hat{\mathrm{~V}}_{\mathrm{IN}}+\mathrm{K}_{\mathrm{r}} \hat{\mathrm{~V}}_{\mathrm{O}} \tag{C.2}
\end{equation*}
$$

where:

$$
\begin{gather*}
\mathrm{K}_{\mathrm{e}}=\frac{\partial \mathrm{I}_{1}}{\partial \mathrm{~V}_{\mathrm{e}}}  \tag{C.3}\\
\mathrm{~K}_{\mathrm{f}}=\frac{\partial \mathrm{I}_{1}}{\partial \mathrm{~V}_{\mathrm{IN}}} \tag{C.4}
\end{gather*}
$$

## C. 1

Fig. C. 1 Control plant representing relationship between average output current $I_{1}$ and control variables $\mathrm{V}_{\mathrm{e}}, \mathrm{V}_{\mathrm{IN}}$, and $\mathrm{V}_{\mathrm{O}}$.

$$
\begin{equation*}
\mathrm{K}_{\mathrm{r}}=\frac{\partial \mathrm{I}_{1}}{\partial \mathrm{~V}_{\mathrm{O}}} \tag{C.5}
\end{equation*}
$$

Equation C. 2 can be represented as a circuit diagram as shown in Fig. C.2.
For the self-oscillating flyback converter, average winding current $\mathrm{I}_{1}$ is expressed as

$$
\begin{equation*}
\mathrm{I}_{1}=\frac{\mathrm{i}_{1}^{\mathrm{pk}}}{2}(1-\mathrm{D})=\mathrm{I}_{\mathrm{O}} \tag{C.6}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{i}_{1}^{\mathrm{pk}}=\mathrm{Ni}_{\mathrm{Sl}}^{\mathrm{pk}}=\mathrm{N} \frac{\mathrm{~V}_{\mathrm{IN}}}{\mathrm{~L}_{\mathrm{M}}} \mathrm{t}_{\mathrm{ON}} . \tag{C.7}
\end{equation*}
$$

From Fig. C.2, on time $\mathrm{t}_{\mathrm{ON}}$ is,

$$
\begin{equation*}
\mathrm{t}_{\mathrm{ON}}=\mathrm{t}_{1}+\mathrm{t}_{2} \tag{C.8}
\end{equation*}
$$

Fig. C. 2 Circuit diagram which represents Eq. (C.2)
where $t_{1}$ represents the time it takes voltage $V_{Q b e}$ to reach the threshold voltage level $V_{\gamma}$,

$$
\begin{equation*}
\mathrm{t}_{1}=\frac{\mathrm{V}_{\gamma}-\mathrm{V}_{\mathrm{e}}}{\mathrm{R}_{\mathrm{S}} \mathrm{~V}_{\mathrm{IN}} / \mathrm{L}_{\mathrm{M}}} \tag{C.9}
\end{equation*}
$$

Fig. C. 3 Base-emitter voltage $\mathrm{V}_{\mathrm{Qve}}$ for a single switching cycle $\mathrm{T}_{\mathrm{S}}$ of self-oscillating flyback converter.
and $t_{2}$ represents the time it takes transistor $Q_{1}$ to discharge input capacitance $C_{\text {ISS }}$ of main switch $\mathrm{S}_{1}$ to the threshold voltage level $\mathrm{V}_{\mathrm{TH}}$.

$$
\begin{equation*}
t_{2}=\text { cons } \tan t . \tag{C.10}
\end{equation*}
$$

Generallly, time $t_{2}$ is constant over the line and load range, and, therefore, can be neglected from a small-signal analysis, i.e., $\hat{\mathfrak{t}}_{1}+\mathrm{t}_{2}=\hat{\mathfrak{t}}_{1}=\hat{\mathfrak{t}}_{\mathrm{ON}}$.

Subsituting Eqs. (C.7)-(C.10) into Eq. (C.6),

$$
\begin{equation*}
\mathrm{I}_{1}=\mathrm{I}_{\mathrm{O}}=\frac{\mathrm{N}}{2 \mathrm{R}_{\mathrm{S}}} \frac{\mathrm{~V}_{\gamma}-\mathrm{V}_{\mathrm{e}}}{1+\mathrm{N} \frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}} \tag{C.11}
\end{equation*}
$$

Taking the derivative of Eq. (C.11) with respect to error voltage $V_{e}$,

$$
\begin{equation*}
\frac{\partial \mathrm{I}_{1}}{\partial \mathrm{~V}_{\mathrm{e}}}=\mathrm{K}_{\mathrm{e}}=-\frac{\mathrm{N}}{2 \mathrm{R}_{\mathrm{S}}\left(1+\mathrm{N} \frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)} \tag{C.12}
\end{equation*}
$$

Taking the derivative of Eq. (C.11) with respect to input voltage $\mathrm{V}_{\text {IN }}$,

$$
\begin{equation*}
\frac{\partial \mathrm{I}_{1}}{\partial \mathrm{~V}_{\mathrm{IN}}}=\mathrm{K}_{\mathrm{f}}=\frac{\mathrm{NV}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}^{2}} \frac{1}{\left(1+\frac{\mathrm{NV}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)^{2}} \tag{C.13}
\end{equation*}
$$

Taking the derivative of Eq. (C.12) with respect to output voltage $\mathrm{V}_{\mathrm{O}}$,

$$
\begin{equation*}
\frac{\partial \mathrm{I}_{1}}{\partial \mathrm{~V}_{\mathrm{O}}}=\mathrm{K}_{\mathrm{r}}=-\frac{\mathrm{N}^{2}}{2} \frac{\left(\mathrm{~V}_{\gamma}-\mathrm{V}_{\mathrm{e}}\right)}{\mathrm{V}_{\mathrm{IN}} \mathrm{R}_{\mathrm{S}}\left(1+\mathrm{N} \frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)^{2}} \tag{C.14}
\end{equation*}
$$

It should be noted that Eqs. (C.12)-(C.14) contains steady-state variables. The steady state expression for error voltage $\mathrm{V}_{\mathrm{e}}$ is obtained from Eq. (C.11), where

$$
\begin{equation*}
\mathrm{V}_{\mathrm{e}}=\mathrm{V}_{\gamma}-\frac{2 \mathrm{I}_{\mathrm{O}} \mathrm{R}_{\mathrm{S}}\left(1+\mathrm{N} \frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)}{\mathrm{N}} \tag{C.15}
\end{equation*}
$$

Substituting into Eq. (C.14),

$$
\begin{equation*}
\mathrm{K}_{\mathrm{r}}=-\frac{\mathrm{I}_{\mathrm{O}} \mathrm{~N}}{\mathrm{~V}_{\mathrm{IN}}\left(1+\mathrm{N} \frac{\mathrm{~V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}\right)} . \tag{C.16}
\end{equation*}
$$

When deriving error-voltage-to-output-voltage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$, it is assumed that $\hat{\mathrm{V}}_{\mathrm{IN}}=0$, and Eq. (C.2) reduces to

$$
\begin{equation*}
\hat{\mathrm{I}}_{1}=\mathrm{K}_{\mathrm{e}} \hat{\mathrm{~V}}_{\mathrm{e}}+\mathrm{K}_{\mathrm{r}} \hat{\mathrm{~V}}_{\mathrm{O}} . \tag{C.17}
\end{equation*}
$$

Relating small-signal current $\hat{\mathrm{I}}_{1}$ to output voltage $\hat{\mathrm{V}}_{\mathrm{O}}$ through impedance Z of the output filter,
where:

$$
\begin{gather*}
\hat{\mathrm{V}}_{\mathrm{O}}=\mathrm{Z} \cdot \hat{\mathrm{I}}_{1}=\frac{\mathrm{Z}_{1} \mathrm{Z}_{2}}{\mathrm{Z}_{1}+\mathrm{Z}_{\mathrm{F}}+\mathrm{Z}_{2}} \hat{\mathrm{I}}_{1}=\mathrm{K}_{\mathrm{e}} \hat{\mathrm{~V}}_{\mathrm{e}}+\mathrm{K}_{\mathrm{r}} \hat{\mathrm{~V}}_{\mathrm{O}},  \tag{C.18}\\
\mathrm{Z}_{1}=\frac{\mathrm{sC}_{\mathrm{O} 1} \mathrm{R}_{\mathrm{CO} 1}+1}{\mathrm{sC} \mathrm{O}_{\mathrm{O} 1}}  \tag{C.19}\\
\mathrm{Z}_{\mathrm{F}}=\mathrm{R}_{\mathrm{Lf}}+\mathrm{sL}_{\mathrm{f}}  \tag{C.20}\\
\mathrm{Z}_{2}=\frac{\mathrm{sC}_{\mathrm{F}} \mathrm{R}_{\mathrm{CF}}+1}{\mathrm{sC} \mathrm{C}_{\mathrm{F}}} \tag{C.21}
\end{gather*}
$$

Solving for output voltage $\hat{\mathrm{V}}_{\mathrm{O}}$,

$$
\begin{equation*}
\frac{\hat{\mathrm{V}}_{\mathrm{O}}}{\hat{\mathrm{~V}}_{\mathrm{e}}}=\frac{\mathrm{Z} \cdot \mathrm{~K}_{\mathrm{e}}}{1-\mathrm{Z} \cdot \mathrm{~K}_{\mathrm{r}}} \tag{C.22}
\end{equation*}
$$

Arranging Eq. (C.22) in pole zero form results in power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$,

$$
\begin{equation*}
\mathrm{G}_{\mathrm{VeVo}}(\mathrm{~s})=\frac{\hat{\mathrm{V}}_{\mathrm{O}}}{\hat{\mathrm{~V}}_{\mathrm{e}}}=\mathrm{M}_{\mathrm{dc}} \cdot \frac{\left(\mathrm{~s} / \mathrm{s}_{\mathrm{z} 1}+1\right)\left(\mathrm{s} / \mathrm{s}_{\mathrm{z} 2}+1\right)}{\left(\mathrm{s} / \mathrm{s}_{\mathrm{p} 1}+1\right)\left(\mathrm{s}^{2} / \omega_{\mathrm{o}}^{2}+\mathrm{s} /\left(\mathrm{Q} \omega_{\mathrm{o}}\right)+1\right)} \tag{C.23}
\end{equation*}
$$

where:

$$
\begin{align*}
& \mathrm{M}_{\mathrm{dc}}=-\frac{\mathrm{V}_{\mathrm{IN}}}{2 \mathrm{R}_{\mathrm{S}} \mathrm{I}_{\mathrm{O}}},  \tag{C.24}\\
& \mathrm{~s}_{\mathrm{zl}}=\frac{1}{\mathrm{C}_{\mathrm{O} 1} \mathrm{R}_{\mathrm{CO} 1}},  \tag{C.25}\\
& \mathrm{~s}_{\mathrm{z} 1}=\frac{1}{\mathrm{C}_{\mathrm{F}} \mathrm{R}_{\mathrm{CF}}},  \tag{C.26}\\
& \mathrm{~s}_{\mathrm{pl}}=-\frac{\mathrm{K}_{\mathrm{r}}}{\mathrm{C}_{\mathrm{O} 1}+\mathrm{C}_{\mathrm{F}}},  \tag{C.27}\\
& \omega_{\mathrm{O}}=\frac{1}{\sqrt{\frac{\mathrm{~L}_{\mathrm{F}}}{\frac{1}{\mathrm{C}_{\mathrm{O} 1}}+\frac{1}{\mathrm{C}_{\mathrm{F}}}}}},  \tag{C.28}\\
& Q=\sqrt{L_{F} \frac{C_{F}+C_{O 1}}{C_{F} C_{O 1}}} \cdot\left(\frac{1}{R_{\mathrm{COI}}+R_{\mathrm{CF}}+\mathrm{R}_{\mathrm{If}}+\mathrm{K}_{\mathrm{r}}\left(\mathrm{R}_{\mathrm{COI}} \mathrm{R}_{\mathrm{CF}}-\frac{\mathrm{L}_{\mathrm{F}}}{\mathrm{C}_{\mathrm{Ol}}+\mathrm{C}_{\mathrm{F}}}\right)}\right) . \tag{C.29}
\end{align*}
$$

## C. 2 Transfer Function $G_{V_{E A} V_{o}}(s)=\hat{V}_{\mathrm{O}} / \hat{\mathrm{V}}_{\mathrm{EA}}$

Generally, the presence of inner loop $\mathrm{T}_{\text {INNER }}$ has the effect of pole shifting on transfer function $G_{V_{E A V O}}(s)$ with respect to power stage transfer function $G_{V e V o}(s)$. This effect can be generalized for any power stage $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$ as

$$
\begin{equation*}
\mathrm{G}_{\mathrm{V}_{\mathrm{eVo}}}(\mathrm{~s})=\frac{\hat{\mathrm{V}}_{\mathrm{O}}}{\hat{\mathrm{~V}}_{\mathrm{e}}}=\mathrm{G} \frac{\mathrm{Z}(\mathrm{~s})}{\mathrm{P}(\mathrm{~s})} \tag{С.30}
\end{equation*}
$$

where $G$ represents dc gain of system, $Z(s)$ represents system zeroes, and $P(s)$ represents system poles. The general expression for transfer function $G_{V_{E A V O}}(s)$ is

$$
\begin{equation*}
\mathrm{G}_{\mathrm{V}_{\mathrm{EAVo}}}(\mathrm{~s})=\frac{\hat{\mathrm{V}}_{\mathrm{O}}}{\hat{\mathrm{~V}}_{\mathrm{EA}}}=\frac{\mathrm{KG}_{\mathrm{VeVo}}(\mathrm{~s})}{1+\mathrm{KG}_{\mathrm{VeVo}}(\mathrm{~s})}=\mathrm{KG} \frac{\mathrm{Z}(\mathrm{~s})}{\mathrm{P}(\mathrm{~s})+\mathrm{KGZ}(\mathrm{~s})}=\mathrm{KG} \frac{\mathrm{Z}(\mathrm{~s})}{\mathrm{P}(\mathrm{~s})^{*}}, \tag{C.31}
\end{equation*}
$$

where

$$
\begin{gather*}
\mathrm{K}=\mathrm{G}_{1} \mathrm{G}_{2} \mathrm{G}_{3},  \tag{C.32}\\
\mathrm{P}(\mathrm{~s})^{*}=\mathrm{P}(\mathrm{~s})+\mathrm{KGZ}(\mathrm{~s}) . \tag{C.33}
\end{gather*}
$$

From Eq. (C.33), it is shown that only the poles $\mathbf{P}(\mathbf{s})$ of the system are affected by the inner loop. The poles $\mathrm{P}(\mathrm{s})^{*}$ of transfer function $\mathrm{G}_{\mathrm{V}_{\mathrm{EAVO}}}(\mathrm{s})$ are shifted with respect to poles $\mathrm{P}(\mathrm{s})$ of power stage transfer function $\mathrm{G}_{\mathrm{VeVo}}(\mathrm{s})$ by dc loop gain KG and by zeroes $\mathrm{Z}(\mathrm{s})$ of the power stage. Similarly, the expression for transfer function $\mathrm{G}_{\mathrm{VEAVO}}(\mathrm{s})$, given in Eq. (4.17), shows evidence of pole shifting. For simplicity, it is assumed that the second stage LC filter, which
consists of filter inductor $L_{F}$ and filter capacitor $C_{F}$, is small, and, therefore, its resonant frequency is relatively high with respect to the bandwidth of inner loop $\mathrm{T}_{\text {INNER }}$. For this case, the only pole which remains below bandwidth $\mathrm{f}_{\text {INNER }}$ of inner loop $\mathrm{T}_{\text {INNER }}$ is pole $\mathrm{s}_{\mathrm{p} 1}$. Considering only poles less than $f_{\text {INNER }}$, transfer function $G_{V_{E A V O}}(s)$ reduces to
where $\mathrm{s}_{\mathrm{pl}}^{*}=\left(1+\mathrm{KM}_{\mathrm{dc}}\right) \mathrm{s}_{\mathrm{p} 1}$.
rewriting Eq. (C.34) to include remaining poles and zeroes,

$$
\begin{equation*}
\mathrm{G}_{\mathrm{V}_{\mathrm{EA} V}}(\mathrm{~s})=\frac{\mathrm{KM}_{\mathrm{dc}}}{1+\mathrm{KM}_{\mathrm{dc}}} \cdot \frac{\left(\mathrm{~s} / \mathrm{s}_{\mathrm{Z} 1}+1\right)\left(\mathrm{s} / \mathrm{s}_{\mathrm{Z} 2}+1\right)}{\left(\mathrm{s} / \mathrm{s}_{\mathrm{p} 1}^{*}+1\right) \mathrm{s}^{2} / \omega_{\mathrm{O}}^{2}+\mathrm{s} / \mathrm{Q} \omega_{\mathrm{O}}+1} \tag{C.35}
\end{equation*}
$$

## C. 3 Sense voltage to error-amplifier -current transfer function $G_{E A}(s)=\hat{i}_{E A} / \hat{V}_{1}$

To facilitate the derivation of the sense voltage $\hat{\mathrm{V}}_{1}$ to error-amplifier current $\hat{\mathrm{i}}_{\text {ea }}$, Fig. C. 4 illustrates the small signal equivalent circuit diagram of the error amplifier TL431. The error amplifier TL431 has been approximated as a dependent current source and resistors $\mathrm{R}_{\mathrm{d} 1}$ and $\mathrm{R}_{\mathrm{d} 2}$ have been represented as a thevenin resistance $\mathrm{R}_{\text {th }}$,

$$
\begin{equation*}
\mathrm{R}_{\mathrm{th}}=\frac{\mathrm{R}_{\mathrm{d} 1} \mathrm{R}_{\mathrm{d} 2}}{\mathrm{R}_{\mathrm{d} 1}+\mathrm{R}_{\mathrm{d} 2}} \tag{C.36}
\end{equation*}
$$

connected to sense voltage $\hat{\mathrm{V}}_{1}$,

$$
\begin{equation*}
\hat{\mathrm{V}}_{1}=\frac{\mathrm{R}_{\mathrm{d} 2}}{\mathrm{R}_{\mathrm{d} 1}+\mathrm{R}_{\mathrm{d} 2}} \hat{\mathrm{~V}}_{\mathrm{O}}=\mathrm{K}_{\mathrm{d}} \hat{\mathrm{~V}}_{\mathrm{O}} \tag{C.37}
\end{equation*}
$$

The compensation components $\mathrm{C}_{\mathrm{EA} 1}, \mathrm{C}_{\mathrm{EA} 2}$, and $\mathrm{R}_{\mathrm{EA} 1}$ are lumped together into impedance block $\mathrm{Z}_{\mathrm{FB}}$ for simplicity.

Small-signal cathode current $\hat{\mathrm{i}}_{\mathrm{k}}$ is $\hat{\mathrm{i}}_{\mathrm{k}}=\mathrm{K}_{\mathrm{O}} \hat{\mathrm{V}}_{\mathrm{r}}$, where $\mathrm{K}_{\mathrm{O}}$ represents the transresistance gain of the error amplifier and voltage $\hat{V}_{r}$ is

$$
\begin{equation*}
\hat{\mathrm{V}}_{\mathrm{r}}=\hat{\mathrm{V}}_{1} \frac{\mathrm{Z}_{\mathrm{FB}}}{\mathrm{Z}_{\mathrm{FB}}+\mathrm{R}_{\mathrm{th}}}+\hat{\mathrm{V}}_{\mathrm{ka}} \frac{\mathrm{R}_{\mathrm{th}}}{\mathrm{Z}_{\mathrm{FB}}+\mathrm{R}_{\mathrm{th}}} \tag{C.38}
\end{equation*}
$$

As transresistance gain $\mathrm{K}_{\mathrm{O}} \rightarrow \infty$, voltage $\hat{\mathrm{V}}_{\mathrm{r}} \rightarrow 0$, and Eq. (C.38) reduces to

Fig. C. 4 Equivalent small-signal model of error amplifier of self-oscillating flyback converter

$$
\begin{equation*}
\mathrm{G}_{\mathrm{EA}}(\mathrm{~s})=\frac{\hat{\mathrm{V}}_{\mathrm{ka}}}{\hat{\mathrm{~V}}_{1}}=-\frac{\mathrm{Z}_{\mathrm{FB}}}{\mathrm{R}_{\mathrm{th}}}, \tag{C.39}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{Z}_{\mathrm{FB}}=\frac{1}{\mathrm{~s}\left(\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}\right)} \frac{\mathrm{sR}_{\mathrm{EA} 1} \mathrm{C}_{\mathrm{EA} 1}+1}{\mathrm{~s} \frac{\mathrm{R}_{\mathrm{EA} 1} \mathrm{C}_{\mathrm{EA} 1} \mathrm{C}_{\mathrm{EA} 2}}{\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}}+1} \tag{C.40}
\end{equation*}
$$

Eq. (C.39) can be written generally as

$$
\begin{equation*}
\mathrm{G}_{\mathrm{EA}}(\mathrm{~s})=\frac{\mathrm{A}}{\mathrm{~s}} \cdot \frac{\mathrm{~s} / \mathrm{s}_{\mathrm{zcomp} 1}+1}{\mathrm{~s} / \mathrm{s}_{\mathrm{pcomp} 2}+1} \tag{C.41}
\end{equation*}
$$

$$
\begin{gather*}
\mathrm{A}=\frac{1}{\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}},  \tag{C.42}\\
\mathrm{~s}_{\mathrm{zcomp1}}=\frac{1}{\mathrm{R}_{\mathrm{EA} 1} \mathrm{C}_{\mathrm{EA} 1}},  \tag{C.43}\\
\mathrm{~s}_{\text {pcomp } 2}=\frac{1}{\mathrm{R}_{\mathrm{EA} 1}} \cdot\left(\frac{1}{\mathrm{C}_{\mathrm{EA} 1}}+\frac{1}{\mathrm{C}_{\mathrm{EA} 2}}\right) . \tag{C.44}
\end{gather*}
$$

## C. 4 Calculations of Error-Amplifier Compensation Component Values

Once the small-signal block diagram is reduced to a single loop system, loop $\mathrm{T}_{1}$ simplifies to

$$
\begin{equation*}
\mathrm{T}_{1}(\mathrm{~s})=\mathrm{K}_{\mathrm{d}} \mathrm{G}_{\mathrm{V}_{\mathrm{EAVo}}}(\mathrm{~s}) \mathrm{G}_{\mathrm{EA}}(\mathrm{~s})=\mathrm{K}_{\mathrm{d}} \cdot \frac{\mathrm{KM}_{\mathrm{dc}}}{1+\mathrm{KM}_{\mathrm{dc}}} \cdot \mathrm{~A} \cdot \frac{\left(\mathrm{~s} / \mathrm{s}_{\mathrm{Z} 1}+1\right)\left(\mathrm{s} / \mathrm{s}_{\mathrm{z} 2}+1\right)}{\left(\mathrm{s} / \mathrm{s}_{\mathrm{p} 1}^{*}+1\right)\left(\mathrm{s}^{2} / \omega_{\mathrm{O}}^{2}+\mathrm{s} / \mathrm{Q} \omega_{\mathrm{O}}+1\right)} \cdot \frac{1}{\mathrm{~s}} \cdot \frac{\left(\mathrm{~s} / \mathrm{s}_{\mathrm{zcompl}}+1\right)}{\left(\mathrm{s} / \mathrm{s}_{\mathrm{pcomp} 2}+1\right)}, \tag{C.45}
\end{equation*}
$$

as given previously in Eq. (4.16), assuming a single shifted pole. Substituting Eq. (4.8), (4.17), and (5.27) into Eq. (C.45) and assuming $\mathrm{s}_{\mathrm{zcomp1}}=\mathrm{s}_{\mathrm{p} 1}^{*}$ and $\mathrm{s}_{\mathrm{pcomp} 2}=8 \pi \mathrm{f}_{\mathrm{C}}$, loop $\mathrm{T}_{1}$ at unity gain crossover frequency $f_{C}$ is,

$$
\begin{equation*}
\mathrm{T}_{1}\left(\mathrm{~s}=2 \pi \mathrm{f}_{\mathrm{C}}\right)=\frac{\mathrm{KM}_{\mathrm{dc}}}{1+\mathrm{KM}_{\mathrm{dc}}} \cdot \frac{1}{\mathrm{R}_{\mathrm{d} 1}\left(\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}\right)} \cdot \frac{0.8}{2 \pi \mathrm{f}_{\mathrm{C}}}=1 \tag{C.46}
\end{equation*}
$$

Solving for $\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}$,

$$
\begin{equation*}
\mathrm{C}_{\mathrm{EA} 1}+\mathrm{C}_{\mathrm{EA} 2}=\frac{0.8 \mathrm{KM}_{\mathrm{dc}}}{1+\mathrm{KM}_{\mathrm{dc}}} \cdot \frac{1}{2 \pi \mathrm{f}_{\mathrm{C}} \mathrm{R}_{\mathrm{d} 1}} \tag{C.47}
\end{equation*}
$$

Selecting $\mathrm{C}_{\mathrm{EA} 2}=\mathrm{C}_{\mathrm{EA} 1} / 10$, compensation capacitor $\mathrm{C}_{\mathrm{EA} 1}$ and $\mathrm{C}_{\mathrm{EA} 2}$ are

$$
\begin{align*}
& \mathrm{C}_{\mathrm{EA} 1}=\frac{0.727}{2 \pi \mathrm{f}_{\mathrm{C}} \mathrm{R}_{\mathrm{d} 1}}  \tag{C.48}\\
& \mathrm{C}_{\mathrm{EA} 2}=\frac{\mathrm{C}_{\mathrm{EA} 1}}{10} \tag{C.49}
\end{align*}
$$

Since compensation zero $s_{z c o m p 1}$ is chosen to cancel pole $s_{p 1}^{*}$, compensation resistor $R_{\text {EA1 }}$ is determined as

$$
\begin{equation*}
\mathrm{R}_{\mathrm{EA} 1}=\frac{1}{\mathrm{C}_{\mathrm{EA} 1}} \cdot \frac{1}{\mathrm{~s}_{\mathrm{p} 1}^{*}} \tag{C.50}
\end{equation*}
$$
